Pub. No. 9

AMERICAN PRACTICAL NAVIGATOR

AN EPITOME OF NAVIGATION

ORIGINALLY BY

NATHANIEL BOWDITCH, LL.D.

Volume II

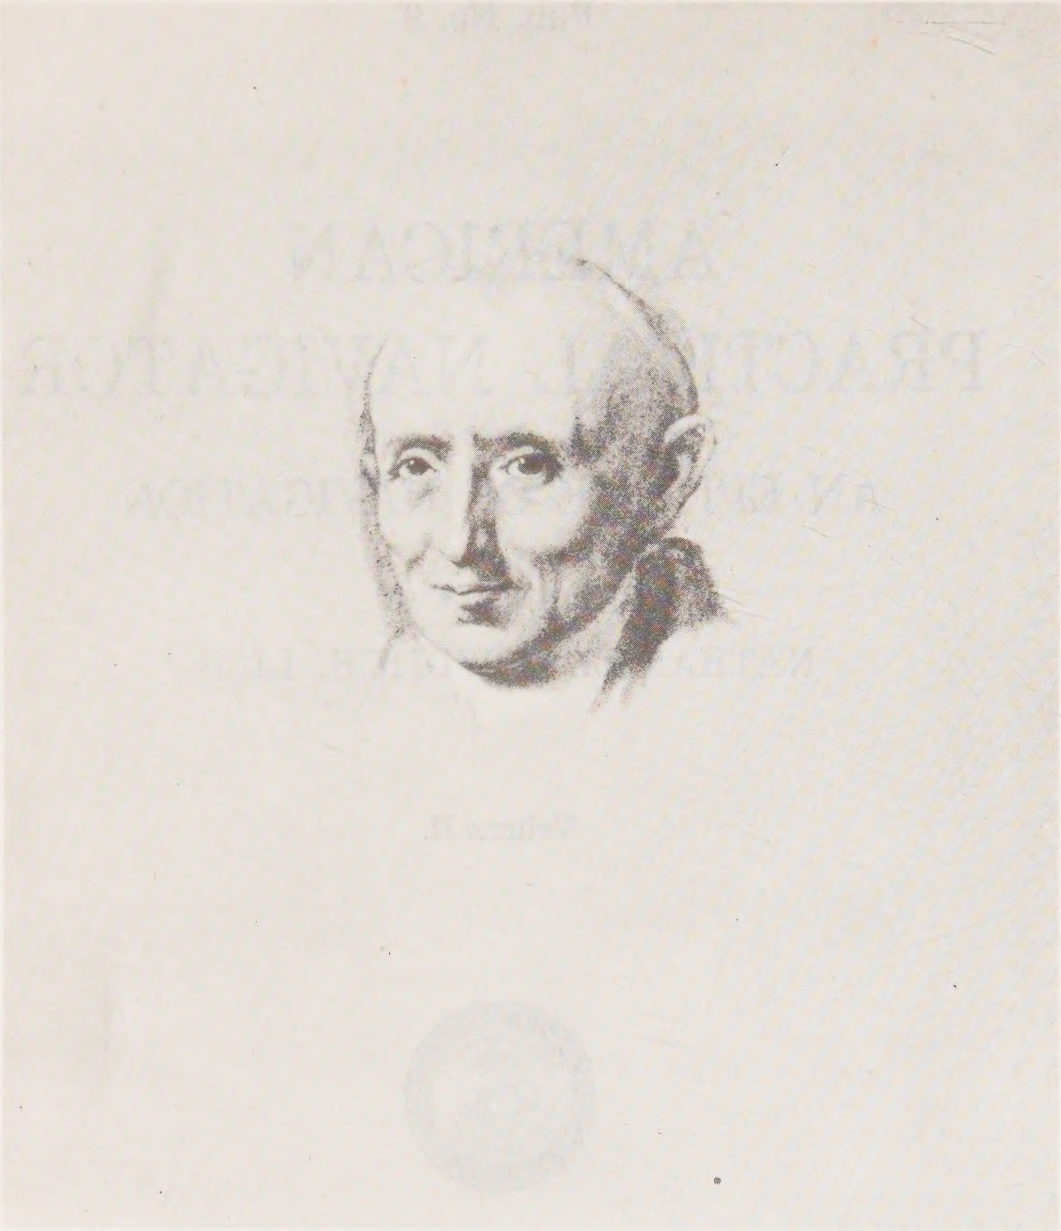

1975 Edition

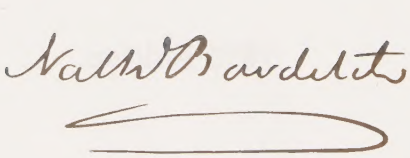

PUBLISHED BY THE

DEFENSE MAPPING AGENCY HYDROGRAPHIC/TOPOGRAPHIC CENTER

For sale by authorized Sale Agents of the Defense Mapping Agency Office of Distribution Services

DMA STOCK NO. NVPUB9V2

Last painting by Gilbert Stuart (1828). Considered by the family of Bowditch to be the best of various paintings made, although it was unfinished when the artist died.

NATHANIEL BOWDITCH

(1773–1838)

Nathaniel Bowditch was born on March 26, 1773, at Salem, Mass., fourth of the seven children of shipmaster Habakkuk Bowditch and his wife, Mary.

Since the migration of William Bowditch from England to the Colonies in the 17th century, the family had resided at Salem. Most of its sons, like those of other families in this New England seaport, had gone to sea, and many of them became shipmasters. Nathaniel Bowditch himself sailed as master on his last voyage, and two of his brothers met untimely deaths while pursuing careers at sea.

It is reported that Nathaniel Bowditch's father lost two ships at sea, and by late Revolutionary days he returned to the trade of cooper, which he had learned in his youth. This provided insufficient income to properly supply the needs of his growing family, and hunger and cold were often experienced. For many years the nearly destitute family received an annual grant of fifteen to twenty dollars from the Salem Marine Society. By the time Nathaniel had reached the age of ten, the family's poverty necessitated his leaving school and joining his father in the cooper's trade.

Nathaniel was unsuccessful as a cooper, and when he was about 12 years of age, he entered the first of two ship-chandlery firms by which he was employed. It was during the nearly ten years he was so employed that his great mind first attracted public attention. From the time he began school Bowditch had an all-consuming interest in learning, particularly mathematics. By his middle teens he was recognized in Salem as an authority on that subject. Salem being primarily a shipping town, most of the inhabitants sooner or later found their way to the ship chandler, and news of the brilliant young clerk spread until eventually it came to the attention of the learned men of his day. Impressed by his desire to educate himself, they supplied him with books that he might learn of the discoveries of other men. Since many of the best books were written by Europeans, Bowditch first taught himself their languages. French, Spanish, Latin, Greek, and German were among the two dozen or more languages and dialects he studied during his life. At the age of 16 he began the study of Newton's *Principia*, translating parts of it from the Latin. He even found an error in that classic, and though lacking the confidence to announce it at the time, he later published his findings and had them accepted.

During the Revolutionary War a privateer out of Beverly, a neighboring town to Salem, had taken as one of its prizes an English vessel which was carrying the philosophical library of a famed Irish scholar, Dr. Richard Kirwan. The books were brought to the Colonies and there bought by a group of educated Salem men who used them to found the Philosophical Library Company, reputed to have been the best library north of Philadelphia at the time. In 1791, when Bowditch was 18, two Harvard-educated ministers, Rev. John Prince and Rev. William Bentley, persuaded the Company to allow Bowditch the use of its library. Encouraged by these two men and a third—Nathan Read, an apothecary and also a Harvard man—Bowditch studied the works of the great men who had preceded him, especially the mathematicians and the astronomers. By the time he became of age, this knowledge, acquired before and after his long working hours and in his spare time, had made young Bowditch the outstanding mathematician in the Commonwealth, and perhaps in the country.

In the seafaring town of Salem, Bowditch was drawn to navigation early, learning the subject at the age of 13 from an old British sailor. A year later he began studying surveying, and in 1794 he assisted in a survey of the town. At 15 he devised an almanac reputed to have been of great accuracy. His other youthful accomplishments included the construction of a crude barometer and a sundial.

When Bowditch went to sea at the age of 21, it was as captain's writer and nominal second mate, the officer's berth being offered him because of his reputation as a scholar. Under Captain Henry Prince, the ship *Henry* sailed from Salem in the winter of 1795 on what was to be a year-long voyage to the Ile de Bourbon (now called Île de la Réunion) in the Indian Ocean.

Bowditch began his seagoing career when accurate time was not available to the average naval or merchant ship. A reliable marine chronometer had been invented some 60 years before, but the prohibitive cost, plus the long voyages without opportunity to check the error of the timepiece, made the large investment an impractical one. A system of determining longitude by "lunar distance," a method which did not require an accurate timepiece, was known, but this product of the minds of mathematicians and astronomers was so involved as to be beyond the capabilities of the uneducated seamen of that day. Consequently, ships navigated by a combination of dead reckoning and parallel sailing (a system of sailing north or south to the latitude of the destination and then east or west to the destination).

To Bowditch, the mathematical genius, computation of lunar distances was no mystery, of course, but he recognized the need for an easier method of working them in order to navigate ships more safely and efficiently. Through analysis and observation, he derived a new and simplified formula during his first trip, a formula which was to open the book of celestial navigation to all seamen.

John Hamilton Moore's *The Practical Navigator* was the leading navigational text when Bowditch first went to sea, and had been for many years. Early in his first voyage, however, the captain's writer-second mate began turning up errors in Moore's book, and before long he found it necessary to recompute some of the tables he most often used in working his sights. Bowditch recorded the errors he found, and by the end of his second voyage, made in the higher capacity of supercargo, the news of his findings in *The Practical Navigator* had reached Edmund Blunt, a publisher at Newburyport, Mass. At Blunt's request, Bowditch agreed to correct Moore's book. The first edition of *The New Practical Navigator* was published in 1799, with correction of the errors Bowditch had found to that time, and with some additional information. The following year a second edition was published with additional corrections. Bowditch eventually found more than 8,000 errors in the work, however, and it was finally decided to completely rewrite the book and to publish it under his own name. In 1802 the first edition of *The New American Practical Navigator* by Nathaniel Bowditch was published, and his vow to put nothing in the book he could not teach every member of his crew served to keep the work within the understanding of the average seaman. In addition to the improved method of determining longitude, Bowditch's book gave the ship's officer information on winds, currents, and tides; directions for surveying; statistics on marine insurance; a glossary of sea terms; instruction in mathematics; and numerous tables of navigational data. His simplified methods, easily grasped by the intelligent seaman willing to learn, paved the way for "Yankee" supremacy of the seas during the clipper ship era.

Two months before sailing for Cadiz on his third voyage, in 1798, Bowditch married Elizabeth Boardman, daughter of a shipmaster. While he was away, his wife died at the age of 18. Two years later, on October 28, 1800, he married his cousin, Mary Ingersoll, she, too, the daughter of a shipmaster. They had eight children.

Bowditch made a total of five trips to sea, over a period of about nine years, his last as master and part owner of the three-masted *Putnam*. Homeward bound from a 13-month voyage to Sumatra and the Ile de France (now called Mauritius) the *Putman* approached Salem harbor on December 25, 1803, during a thick fog without having had a celestial observation since noon on the 24th. Relying upon his dead reckoning, Bowditch conned his wooden-hulled ship to the entrance of the rocky harbor, where he had the good fortune to get a momentary glimpse of Eastern Point, Cape Ann, enough to confirm his position. The *Putnam* proceeded in, past such hazards as "Bowditch's Ledge" (named after a great-grandfather who had wrecked his ship on the rock more than a century before) and anchored safely at 1900 that evening. Word of the daring feat, performed when other masters were hove-to outside the harbor, spread along the coast and added greatly to Bowditch's reputation. He was, indeed, the "practical navigator."

His standing as a mathematician and successful shipmaster earned him a lucrative (for those times) position ashore within a matter of weeks after his last voyage. He was installed as president of a Salem fire and marine insurance company, at the age of 30, and during the 20 years he held that position the company prospered. In 1823 he left Salem to take a similar position with a Boston insurance firm, serving that company with equal success until his death.

From the time he finished the "*Navigator*" until 1814, Bowditch's mathematical and scientific pursuits consisted of studies and papers on the orbits of comets, applications of Napier's rules, magnetic variation, eclipses, calculations on tides, and the charting of Salem harbor. In that year, however, he turned to what he considered the greatest work of his life, the translation into English of *Mécanique Céleste*, by Pierre Laplace. *Mècanique Cèleste* was a summary of all the then known facts about the workings of the heavens. Bowditch translated four of the five volumes before his death, and published them at his own expense. He gave many formula derivations which Laplace had not shown, and also included further discoveries following the time of publication. His work made this information available to American astronomers and enabled them to pursue their studies on the basis of that which was already known. Continuing his style of writing for the learner, Bowditch presented his English version of *Mècanique Cèleste* in such a manner that the student of mathematics could easily trace the steps involved in reaching the most complicated conclusions.

Shortly after the publication of *The New American Practical Navigator*, Harvard College honored its author with the presentation of the honorary degree of Master of Arts, and in 1816 the college made him an honorary Doctor of Laws. From the time the Harvard graduates of Salem first assisted him in his studies, Bowditch had a great interest in that college, and in 1810 he was elected one of its Overseers, a position he held until 1826, when he was elected to the Corporation. During 1826–27 he was the leader of a small group of men who saved the school from financial disaster by forcing necessary economies on the college's reluctant president. At one time Bowditch was offered a Professorship in Mathematics at Harvard but this, as well as similar offers from West Point and the University of Virginia, he declined. In all his life he was never known to have made a public speech or to have addressed any large group of people.

Many other honors came to Bowditch in recognition of his astronomical, mathematical, and marine accomplishments. He became a member of the American Academy of Arts and Sciences, the East India Marine Society, the Royal Academy of Edinburgh, the Royal Society of London, the Royal Irish Academy, the American Philosophical Society, the Connecticut Academy of Arts and Sciences, the Boston Marine Society,

the Royal Astronomical Society, the Palermo Academy of Science, and the Royal Academy of Berlin.

Nathaniel Bowditch outlived all of his brothers and sisters by nearly 30 years. Death came to him on March 16, 1838, in his sixty-fifth year. The following eulogy by the Salem Marine Society indicates the regard in which this distinguished American was held by his contemporaries:

"In his death a public, a national, a human benefactor has departed. Not this community, nor our country only, but the whole world, has reason to do honor to his memory. When the voice of Eulogy shall be still, when the tear of Sorrow shall cease to flow, no monument will be needed to keep alive his memory among men; but as long as ships shall sail, the needle point to the north, and the stars go through their wonted courses in the heavens, the name of Dr. Bowditch will be revered as of one who helped his fellow-men in a time of need, who was and is a guide to them over the pathless ocean, and of one who forwarded the great interests of mankind."

The New American Practical Navigator was revised by Nathaniel Bowditch several times after 1802 for subsequent editions of the book. After his death, Jonathan Ingersoll Bowditch, a son who made several voyages, took up the work and his name appeared on the title page from the eleventh edition through the thirty-fifth, in 1867. In 1868 the newly organized U.S. Navy Hydrographic Office bought the copyright. Revisions have been made from time to time to keep the work in step with navigational improvements. The name has been altered to the *American Practical Navigator*, but the book is still commonly known as "Bowditch." A total of more than 850,000 copies has been printed in about 70 editions during the more than a century and a half since the book was first published in 1802. It has lived because it has combined the best thoughts of each generation of navigators, who have looked to it as their final authority.

PREFACE

This epitome of navigation has been maintained continuously since it was first published in 1802. The U.S. Navy maintained "Bowditch" from 1868 until 1972, when the Defense Mapping Agency Hydrographic Center was assigned the responsibility for its publication.

This volume of the extensively revised edition provides the tables, formulas, data, and instructions needed by the navigator to perform many of the computations associated with dead reckoning, piloting, and celestial navigation.

The intent of the original author to provide a compendium of navigational material understandable to the mariner has been consistently followed. However, navigation is not presented as a mechanical process to be followed blindly. Rather, emphasis has been given to the fact that the aids provided by *science* can be used effectively to improve the *art* of navigation only if a well-informed person of mature judgment and experience is on hand to interpret information as it becomes available. Thus, the facts needed to perform the mechanics of navigation have been supplemented with additional material intended to help the navigator acquire perspective in meeting the various needs that arise.

Many institutions, organizations, groups, and individuals have assisted in the preparation of volume II, but all of the material has been edited by one individual to assure continuity and consistency. Particular acknowledgment is given the following: Dr. P. Kenneth Seidelmann, Assistant Director, Nautical Almanac Office, U.S. Naval Observatory, for his assistance in matters pertaining to the almanacs and related topics; Dr. William H. Guier for the improved table 9; Captain Wayne M. Waldo and Mr. Richard M. Plant, Maritime Institute of Technology and Graduate Studies, Linthicum Heights, Maryland, and Lieutenant Commander Guy P. Clark, U.S. Coast Guard, for their contributions to chapter XII; Rear Commander Allan E. Bayless, N, and Past Staff Commander O. B. Ellis, N, U.S. Power Squadrons, for their assistance in examining the text for errors; Commander Frank E. Bassett, U.S. Navy, Chairman, Lieutenant Commander Arthur J. Tuttle, U.S. Navy, and Lieutenant Commander Richard A. Smith, Royal Navy, of the Department of Navigation, Division of Naval Command and Management, United States Naval Academy, for their guidance in practical areas; the U.S. Power Squadrons for suggestions relating to the graph of article 1106 for height of tide determination, and table 35; and many individuals, especially the marine navigation instructors and experienced practicing navigators who have responded to our questionnaires and offered constructive suggestions or directed attention to errors in previous editions.

Users should refer corrections, additions, and comments for improving this product to DIRECTOR, DEFENSE MAPPING AGENCY HYDROGRAPHIC/TOPOGRAPHIC CENTER, Washington, D.C. 20315, ATTN: Code PRH.

EXPLANATION OF TABLES

Table 1. Conversion Angle.—The angles listed in this table are the differences between the great-circle and rhumb line (Mercator) directions between various points. The table is used in converting radio bearings to equivalent rhumb line bearings for plotting on a Mercator chart. The sign to be used is indicated at the bottom of the table.

The first one and one-half pages of the table, for differences of longitude of not more than 4°.5, and middle latitudes between 0° and 85°, is intended primarily for use in converting radio bearings observed near a coast. In high latitudes it may be needed for converting visual bearings of objects a considerable distance away.

In high latitudes it is not unusual to make use of bearings on objects a considerable distance from the vessel. Because of the rapid convergence of the meridians in these areas, such bearings are not correctly represented by straight lines on a Mercator chart. If this projection is used, the bearings should be corrected in the same manner that radio bearings are corrected, since both can be considered great circles. This part of the table is entered with (1) the middle latitude between the craft and radio station or object, and (2) the difference of longitude between these two points. Do not use this part of the table if the latitudes are of contrary name (one north, the other south), if the difference of latitude is more than 10°, or if the difference of longitude is more than 4°.5. Under any of these conditions, use the second part of the table. For this part, the entering arguments are (1) the latitude of the receiver, (2) the difference of longitude (DLo) between the two points involved, and (3) the latitude of the transmitter. For accurate results, use triple interpolation (art. 204).

Use of the table is explained in article 1402.

The conversion angles on the first one and one-half pages of the table were computed by means of the formula:

$$\tan \text{conversion angle} = \sin \text{Lm} \tan \tfrac{1}{2} \text{DLo},$$

in which Lm is the middle latitude, and DLo is the difference of longitude. This formula is based upon the assumption that the plot of a great-circle track on a Mercator chart is symmetrical, the axis of symmetry being the perpendicular bisector of the rhumb line connecting the two points. No error of practical significance in ordinary navigation is introduced by this erroneous assumption over the range covered by the first one and one-half pages of the table.

The remainder of the table was computed by means of the formula: conversion angle = initial great-circle direction ~ rhumb line direction. The initial great-circle directions were computed by means of the formula:

$$\text{hav } C = \csc D \sec L_1 [\text{hav co } L_2 - \text{hav } (D \sim \text{co } L_1)],$$

in which C is the initial great-circle direction, D is the great-circle distance in arc units, L_1 is the latitude of departure (or receiver), and L_2 is the latitude of the destination (or transmitter). The distance D was computed by means of the formula:

$$\text{hav } D = \text{hav DLo} \cos L_1 \cos L_2 + \text{hav } (L_1 \sim L_2),$$

in which the notation is the same as above.

The rhumb line directions were computed by means of the formula:

$$\tan C = \frac{\text{DLo}}{m},$$

in which C is the rhumb line direction, and $m = M_1 \sim M_2$, the meridional parts of the two latitudes.

Table 2. Conversion of Compass Points to Degrees.—In this table the compass is boxed to 128 quarter points and the equivalent angle is given in degrees, minutes, and seconds. The naming of the quarter points, as given here, is one of several systems that have been used.

Table 3. Traverse Table.—This table can be used in the solution of the usual problems encountered in any of the sailings except great-circle and composite. In providing the values of the difference of latitude and departure corresponding to distances up to 600 miles and for courses for every degree of the compass, table 3 is essentially a tabulation of the solutions of plane right triangles. Since the solutions are for integral values of the acute angle and the distance, interpolation for intermediate values may be required. Through appropriate interchanges of the headings of the columns, solutions for other than plane sailings can be effected. The interchanges of the headings of the different columns are summarized at the foot of each table opening.

The distance, difference of latitude, and departure columns are labeled Dist., D.Lat., and Dep., respectively.

For the solution of the plane right triangle, any number N in the distance column is the hypotenuse; the number opposite in the difference of latitude column is N times the cosine of the acute angle; and the other number opposite in the departure column is N times the sine of the acute angle. Or, the number in the column labeled D.Lat. is the value of the side adjacent and the number in the column labeled Dep. is the value of the side opposite the acute angle.

The use of this table in the solution of problems of the various sailings is given in chapter X.

Table 4. Table of Offsets.—This table gives the corrections to the straight line of position (LOP) as drawn on a chart or plotting sheet to provide a closer approximation of the arc of the circle of equal altitude, a small circle of radius equal to the zenith distance.

In adjusting the straight LOP to obtain a closer approximation of the arc of the circle of equal altitude, points on the LOP are offset at right angles to the LOP in the direction of the celestial body. The arguments for entering the table are the distance from the DR to the foot of the perpendicular and the altitude of the body.

The table was computed by means of the formulas:

$$R = 3438' \cot h$$

$$\sin \theta = D/R$$

$$X = R(1 - \cos \theta),$$

in which X is the offset, R is the radius of a circle of equal altitude for altitude h, and D is the distance from the intercept to the point on the LOP to be offset.

Table 5. Meridional Parts.—In this table the meridional parts used in the construction of Mercator charts and in Mercator sailing are tabulated to one decimal place for each minute of latitude from the equator to the poles. The use of the table is explained in article 1007.

The table was computed by means of the formula:

$$M = a \log_e 10 \log \tan \left(45° + \frac{L}{2}\right) - a\left(e^2 \sin L + \frac{e^4}{3} \sin^3 L + \frac{e^6}{5} \sin^5 L + \ldots\right),$$

In which

M is the number of meridional parts between the equator and the given latitude, a is the equatorial radius of the earth, expressed in minutes of arc of the equator, or

$$a = \frac{21{,}600}{2\pi} = 3437.74677078 \ (\log = 3.5362738827),$$

$\log_e$ is the natural (Naperian) logarithm, using the base e=2.71828182846,
$\log_e 10$=2.30258509299 (log=0.3622156886),
L is the latitude,
e is the ellipticity of the earth, or $\sqrt{2f-f^2}$=0.08227185422 (log=8.9152512855−10),
and
f is the flattening of the earth, or $f=\frac{1}{294.98}$=0.00339006034 (log=7.5302074283−10).

Using these values,
$a \log_e 10$=7915.704468 (log=3.8984895715)
ae^2=23.268932 (log=1.3667764504)
$\frac{ae^4}{3}$=0.052500 (log=8.7201593034−10)
$\frac{ae^6}{5}$=0.000213 (log=6.3283796034−10).

Hence, the formula becomes

$$M=7915.704468 \log \tan\left(45°+\frac{L}{2}\right)-23.268932 \sin L-0.052500 \sin^3 L-0.000213 \sin^5 L \ldots$$

The constants used in this derivation and in the table are based upon the Clarke spheroid of 1866 (app. D), the standard reference spheroid used for charting North America.

Table 6. Length of a Degree of Latitude and Longitude.—This table gives the length of one degree of latitude and longitude at intervals of 1° from the equator to the poles. In the case of latitude, the values given are the lengths of the arcs extending half a degree on each side of the tabulated latitudes. Lengths are given in nautical miles, statute miles, feet, and meters.

The values were computed in meters, using the Clarke spheroid of 1866 (app. D), and converted to other units by the factors given in appendix D. The following formulas were used:

$$M=111{,}132.09-566.05 \cos 2L+1.20 \cos 4L-0.002 \cos 6L+ \ldots$$
$$P=111{,}415.13 \cos L-94.55 \cos 3L+0.12 \cos 5L- \ldots$$

in which M is the length of 1° of the meridian (latitude), L is the latitude, and P is the length of 1° of the parallel (longitude).

Table 7. Distance of an Object by Two Bearings.—To determine the distance of an object as a vessel on a steady course passes it, observe the differences between the course and two bearings of the object, and note the time interval between bearings. Enter this table with the two differences. Multiply the distance run between bearings by the number in the first column to find the distance of the object at the time of the second bearing, and by the number in the second column to find the distance when abeam. Use of the table is explained in article 1204.

The table was computed by solving plane oblique and right triangles (art. 142).

Table 8. Distance of the Horizon.—This table gives the distance, in nautical and statute miles, of the visible horizon for various heights of eye from 1 to 200,000 feet. The actual distance varies somewhat as refraction changes. Also, the formulas used contain an approximation which introduces an error of a few tenths of a mile at the greatest heights tabulated. However, the error is generally less than that introduced by nonstandard atmospheric conditions. Since the earth's ellipticity is not considered, the table can be used at any place on the earth, without appreciable error.

Use of the table is explained in article 1206.

The table was computed by means of the formulas:

$$\text{nautical miles: } D=1.144\sqrt{h},$$
$$\text{statute miles: } D=1.317\sqrt{h},$$

in which D is the distance of the horizon in miles, and h is the height above the surface in feet. The constants 1.144 and 1.317 are based upon the mean radius of the earth according to the Clarke spheroid of 1866 (app. D).

Table 9. Distance by Vertical Angle.—This table provides means for determining the distance of an object of known height above sea level. The vertical angle between the top of the object and the visible (sea) horizon (the sextant altitude) is measured and corrected for index error and dip only. If the visible horizon is not available as a reference, the angle should be measured to the bottom of the object, and dip short of the horizon (tab. 22) used in place of the usual dip correction. This may require several approximations of distance by alternate entries of tables 9 and 22 until the same value is obtained twice. The table is entered with the difference in the height of the object and the height of eye of the observer, in feet, and the corrected vertical angle; and the distance in nautical miles is taken directly from the table. An error may be introduced if refraction differs from the standard value used in the computation of the table. Use of the table is explained in article 1203.

The derivation of the formula used in the computation of the table is given in the article entitled "Note on Determining Range from Sextant Altitude" by Dr. William H. Guier, published in NAVIGATION: *Journal of the Institute of Navigation*, Vol. 15, No. 4, Winter 1968–69, pp. 366–75.

Table 9 is a modification of Tables I, II, and III of Dr. Guier's article, which is copyrighted by The Institute of Navigation, Washington, D.C. The data from Tables I, II, and III are used with the permission of the Institute of Navigation, Washington, D.C.

Table 10. Direction and Speed of True Wind.—This table provides a means of converting apparent wind, observed aboard a moving craft, to true wind. To use the table, divide the apparent wind, in knots, by the vessel's speed, also in knots. This gives the apparent wind speed in units of ship's speed. Enter the table with this value and the difference between the heading and the apparent wind direction. The values taken from the table are (1) the difference between the heading and the true wind direction, and (2) the speed of the true wind in units of ship's speed. The true wind is on the same side as the apparent wind, and from a point farther aft. To convert wind speed in units of ship's speed to speed in knots, multiply by the vessel's speed in knots. The steadiness of the wind and the accuracy of its measurement are seldom sufficient to warrant interpolation in this table. If speed of the true wind and relative direction of the apparent wind are known, enter the column for direction of the apparent wind, and find the speed of the true wind, in units of ship's speed. The number to the left is the relative direction of the true wind. The number on the same line in the side columns is the speed of the apparent wind in units of ship's speed. Two solutions are possible if speed of the true wind is less than the ship's speed.

The table was computed by solving the triangle involved in a graphical solution, using the formulas:

$$\tan \alpha = \frac{\sin B_A}{S_A - \cos B_A},$$

$$B_T = B_A + \alpha,$$

$$S_T = \frac{\sin B_A}{\sin \alpha},$$

in which α is an auxiliary angle, B_A is the difference between the heading and the apparent wind direction, S_A is the speed of the apparent wind in units of ship's speed, B_T is the difference between the heading and the true wind direction, and S_T is the speed of the true wind in units of ship's speed.

Table 11. Correction of Barometer Reading for Height Above Sea Level.—If simultaneous barometer readings at different heights are to be of maximum value in weather analysis, they should be converted to the corresponding readings at a standard height, usually sea level. To convert the observed barometer reading to this level, enter this

table with the outside temperature and the height of the barometer above sea level. The height of a barometer is the height of its sensitive element; in the case of a mercurial barometer, this is the height of the free surface of mercury in the cistern. The correction taken from this table applies to the readings of any type barometer, and is always *added* to the observed readings, unless the barometer is below sea level.

The correction was computed by means of the formula:

$$C=29.92126\left[1-\frac{1}{\text{antilog}\left(\frac{0.0081350\,H}{T+0.00178308\,H}\right)}\right]$$

in which

C is the correction in inches of mercury,

H is the height of the barometer above sea level in feet, and,

T is the mean temperature, in degrees Rankine (degrees Fahrenheit plus 459°.67), of the air between the barometer and sea level. At sea, the outside air temperature is sufficiently accurate for this purpose.

Table 12. Correction of Barometer Reading for Gravity.—The height of the mercury column of a mercurial barometer is affected by the force of gravity, which changes with latitude and is approximately equal along any parallel of latitude. The average gravitational force at latitude 45°32′40″ is used as the standard for calibration. This table provides a correction to convert the observed reading at any other latitude to the corresponding value at latitude 45°32′40″, so that it will have maximum value in weather analysis of an area. Enter the table with the latitude, take out the correction, and apply in accordance with the sign given. The correction does not apply to aneroid barometers.

The correction was computed by means of the formula:

$$C=B\ (-0.002637\cos 2L+0.000006\cos^2 2L-0.000050),$$

in which

C is the correction in inches,

B is the observed reading of the barometer (corrected for temperature and instrumental errors) in inches of mercury. This table was computed for a standard height of 30 inches, and

L is the latitude.

Table 13. Correction of Barometer Reading for Temperature.—Because of the difference in expansion of the mercury column of a mercurial barometer and that of the brass scale by which the height is measured, a correction should be applied to the reading when the temperature differs from the standard used for calibration of the instrument. To find the correction, enter this table with the temperature in degrees Fahrenheit, and the barometer reading. Apply the correction in accordance with the sign given. This correction does not apply to aneroid barometers.

The standard temperature used for calibration is 32° F for the mercury, and 62° F for the brass. The correction was computed by means of the formula:

$$C=-B\,\frac{m\,(T-32°)-l\,(T-62°)}{1+m\,(T-32°)},$$

in which

C is the correction in inches,

B is the observed reading of the barometer in inches of mercury,

m is the coefficient of cubical expansion of mercury = 0.0001010 cubic inches per degree F,

l is the coefficient of linear expansion of brass = 0.0000102 inches per degree F, and

T is the temperature of the attached thermometer in degrees F.

Substituting the values for m and l and simplifying:

$$C=-B\,\frac{T-28°.630}{1.1123\,T+10978°}.$$

The minus sign before B indicates that the correction is negative if the temperature is more than 28°.630.

Table 14. Conversion Table for Millibars, Inches of Mercury, and Millimeters of Mercury.—The reading of a barometer in inches or millimeters of mercury corresponding to a given reading in millibars can be found directly from this table.

The formula for the pressure in millibars is:

$$P=\frac{B_m D g}{1000},$$

in which

P is the atmospheric pressure in millibars,
B_m is the height of the column of mercury in millimeters,
D is the density of mercury = 13.5951 grams per cubic centimeter, and
g is the standard value of gravity = 980.665 dynes. Substituting numerical values:

$$P=1.33322\,B_m,$$

and

$$B_m=\frac{P}{1.33322}=0.750064P.$$

Since one millimeter = 0.03937 inches,

$$B_i=\frac{0.03937\,P}{1.33322}=0.0295300\,P,$$

in which B_i is the height of the column of mercury, in inches.

Table 15. Conversion Table for Thermometer Scales.—Enter this table with temperature Fahrenheit, F; Celsius (centigrade), C; or Kelvin, K; and take out the corresponding readings on the other two temperature scales.

On the Fahrenheit scale, the freezing temperature of pure water at standard sea-level pressure is 32°, and the boiling point under the same conditions is considered 212°. The corresponding temperatures are 0° and 100°, respectively, on the Celsius scale and 273°.15 and 373°.15, respectively, on the Kelvin scale. The value of (−) 273°.15 C for absolute zero, the starting point of the Kelvin scale, is the value recognized officially by the National Bureau of Standards of the United States.

The formulas for converting the reading of one scale to the corresponding values of the others, derived from the figures given above, are:

$$C=\frac{5}{9}(F-32°)=K-273°.15,$$

$$F=\frac{9}{5}C+32°=\frac{9}{5}K-459°.67,$$

$$K=\frac{5}{9}(F+459°.67)=C+273°.15,$$

in which all temperatures are in degrees.

Table 16. Relative Humidity.—To determine the relative humidity of the atmosphere, enter this table with the dry-bulb (air) temperature (F), and the *difference* between the dry-bulb and wet-bulb temperatures (F). The value taken from the table is the approximate percentage of relative humidity. If the dry-bulb and wet-bulb temperatures are the same, relative humidity is 100 percent.

The table was computed by means of the formula:

$$R=\frac{100\,e}{e_w},$$

in which

R is the approximate relative humidity in percent,
e is the ambient vapor pressure, and
e_w is the saturation vapor pressure over water at dry-bulb temperature.
Professor Ferrel's psychrometric formula was used for computation of e:

$$e=e'-\left[0.000367\,P\,(t-t')\left(1+\frac{t'-32°}{1571}\right)\right],$$

in which

e is the ambient vapor pressure in millibars,

e′ is the saturation vapor pressure in millibars at wet-bulb temperature with respect to water,

P is the atmospheric pressure (the millibar equivalent of 30 inches of mercury is used for this table),

t is the dry-bulb temperature in degrees Fahrenheit, and

t′ is the wet-bulb temperature in degrees Fahrenheit.

The values of e_w were taken from the International Meteorological Organization Publication Number 79, 1951, table 2, pages 82–83.

Table 17. Dew Point.—To determine the dew point, enter this table with the dry-bulb (air) temperature (F), and the *difference* between the dry-bulb and wet-bulb temperatures (F). The value taken from the table is the dew point in degrees Fahrenheit. If the dry-bulb and wet-bulb temperatures are the same, the air is at or below the dew point.

The values given in this table were obtained (1) by determining the saturation vapor pressure e′ for the given temperature T (in degrees Rankine) by means of the following formula:

$$\log_{10} e' = -7.90298\left(\frac{671.67}{T}-1\right)+5.02808\log_{10}\frac{671.67}{T}-1.3816\times10^{-7}\left(10^{11.344\left(1-\frac{T}{671.67}\right)}-1\right)$$

$$+8.1328\times10^{-3}\left(10^{-3.49149\left(\frac{671.67}{T}-1\right)}-1\right)+\log_{10}1013.246,$$

(2) by determining the ambient vapor pressure by means of Ferrel's formula (see explanation to table 16), (3) by substituting e for e′ in the formula of (1) to obtain the temperature T of the wet bulb when saturation occurs (to the precision of table 17), and (4) by converting the wet-bulb temperature (T) to the dry-bulb temperature T′ by means of the equation:

$$T' = T+(t-t'),$$

where (t−t′) is the depression of the wet-bulb temperature. Tables evaluating e′ in terms of T for use in steps (1) and (3) are given in International Meteorological Organization Publication Number 79, 1951, and the Smithsonian Meteorological Tables, Sixth Revised Edition, 1951.

Table 18. Speed Table for Measured Mile.—To find the speed of a vessel traversing a measured nautical mile in a given number of minutes and seconds of time, enter this table at the top or bottom with the number of minutes, and at either side with the number of seconds. The number taken from the table is speed in knots. Accurate results can be obtained by interpolating to the nearest 0.1 second.

This table was computed by means of the formula:

$$S=\frac{3600}{T},$$

in which S is speed in knots, and T is elapsed time in seconds.

Table 19. Speed, Time, and Distance.—To find the distance steamed at any given speed between 0.5 and 40 knots in any given number of minutes from 1 to 60, enter this table at the top with the speed, and at the left with the number of minutes. The number taken from the table is the distance in nautical miles. If hours are substituted for minutes, the tabulated distance should be multiplied by 60; if seconds are substituted for minutes, the tabulated distance should be divided by 60. Use of the table is explained in article 1202.

The table was computed by means of the formula:

$$D=\frac{ST}{60},$$

in which D is distance in nautical miles, S is speed is knots, and T is elapsed time in minutes.

Table 20. Conversion Table for Nautical and Statute Miles.—This table gives the number of statute miles corresponding to any whole number of nautical miles from 1 to 100, and the number of nautical miles corresponding to any whole number of statute miles within the same range. The entering value can be multiplied by any power of 10, including negative powers, if the corresponding value of the other unit is multiplied by the same power. Thus, 2,700 nautical miles are equivalent to 3,107.1 statute miles, and 0.3 statute mile is equivalent to 0.2607 nautical mile. Hence, to find the number of statute miles equal to 2463.2 nautical miles:

Nautical miles	*Statute miles*
2400.0	2761.9
63.0	72.5
0.2	0.2
2463.2	2834.6

The table was computed by means of the conversion factors of appendix D:
1 nautical mile=1.15077945 statute miles,
1 statute mile=0.86897624 nautical mile.

Table 21. Conversion Table for Meters, Feet, and Fathoms.—The number of feet and fathoms corresponding to a given number of meters, and vice versa, can be taken directly from this table for any value of the entering argument from 1 to 120. The entering value can be multiplied by any power of 10, including negative powers, if the corresponding values of the other units are multiplied by the same power. Thus, 420 meters are equivalent to 1378.0 feet, and 11.2 fathoms are equivalent to 20.483 meters. Hence, to find the number of meters equal to 2163 feet:

Feet	*Meters*
2100	640
63	19
2163	659.

The table was computed by means of the relationships given in appendix D:
1 meter =39.370079 inches,
1 foot =12 inches,
1 fathom=6 feet.

Approximately the same results would be obtained by using the direct conversion factors given in appendix D.

Table 22. Dip of the Sea Short of the Horizon.—If land, another vessel, or other obstruction is between the observer and the sea horizon, use the waterline of the obstruction as the horizontal reference for altitude measurements, and substitute dip from this table for the dip of the horizon (height of eye correction) given in the *Nautical Almanac* or other source. The values below the bold rules are for normal dip, the visible horizon being between the observer and the obstruction. Use of the table is explained in articles 726 and 1203 and in the explanation of table 9.

The table was computed by means of the formula:

$$D_s=0.4156d+0.5658\frac{h}{d},$$

in which D_s is the dip short of the sea horizon, in minutes; d is the distance to the waterline of the obstruction, in nautical miles; and h is the height of eye of the observer above sea level, in feet.

Table 23. Altitude Correction for Air Temperature.—This table provides a correction to be applied to the altitude of a celestial body when the air temperature varies from the 50° F used for determining mean refraction by means of the *Nautical Almanac*. For maximum accuracy, apply index correction and dip to sextant altitude first, obtaining apparent (rectified) altitude for use in entering this table. Enter the table with altitude and air temperature in degrees Fahrenheit. Apply the correction, in accordance with its tabulated sign, to altitude. Use of the table is explained principally in chapter VIII, and especially in articles 807 and 827.

The table was computed by means of formula:

$$\text{Correction} = R_m\left(1-\frac{510}{460+T}\right),$$

in which R_m is mean refraction and T is temperature in degrees Fahrenheit.

Table 24. Altitude Correction for Atmospheric Pressure.—This table provides a correction to be applied to the altitude of a celestial body when the atmospheric pressure varies from the 29.83 inches (1010 millibars) used for determining mean refraction by means of the *Nautical Almanac*. For most accurate results, apply index correction and dip to sextant altitude first, obtaining apparent (rectified) altitude for use in entering this table. Enter the table with altitude and atmospheric pressure. Apply the correction to altitude, *adding* if the pressure is less than 29.83 inches and *subtracting* if it is more than 29.83 inches. Use of the table is explained principally in chapter VIII, and especially in articles 808 and 827.

The table was computed by means of the formula:

$$\text{Correction} = R_m\left(1-\frac{P}{29.83}\right),$$

in which R_m is mean refraction and P is atmospheric pressure in inches of mercury.

Table 25. Meridian Angle and Altitude of a Body on the Prime Vertical Circle.—A celestial body having a declination of contrary name to the latitude does not cross the prime vertical above the celestial horizon, its nearest approach being at rising or setting.

If the declination and latitude are of the same name, and the declination is numerically greater, the body does not cross the prime vertical, but makes its nearest approach (in azimuth) when its meridian angle, east or west, and altitude are as shown in this table, these values being given in italics above the heavy line. At this time the body is stationary in azimuth.

If the declination and latitude are of the same name and numerically equal, the body passes through the zenith as it crosses both the celestial meridian and the prime vertical, as shown in the table.

If the declination and latitude are of the same name, and the declination is numerically less, the body crosses the prime vertical when its meridian angle, east or west, and altitude are as tabulated in vertical type below the heavy line.

The table is entered with declination of the celestial body and the latitude of the observer. Computed altitudes are given, no allowance having been made for refraction, dip, parallax, etc. The tabulated values apply to any celestial body, but values are not given for declination greater than 23° because the tabulated information is generally desired for the sun only. Use of the information given in this table is discussed in articles 710 and 721.

The table was computed by means of the following formulas, derived by Napier's rules (art. 142):

Nearest approach (in azimuth) to the prime vertical:

$$\csc h = \sin d \csc L,$$
$$\sec t = \tan d \cot L.$$

On the prime vertical:

$$\sin h = \sin d \csc L,$$
$$\cos t = \tan d \cot L.$$

In these formulas, h is the altitude, d is the declination, L is the latitude, t is the meridian angle.

Table 26. Latitude and Longitude Factors.—The latitude obtained by solution of an ex-meridian sight (art. 732) is inaccurate if the longitude used in determining the meridian angle is incorrect. Similarly, the longitude obtained by solution of a time sight (volume I) is inaccurate if the latitude used in the solution is incorrect, unless the celestial body is on the prime vertical. This table gives the errors resulting from unit errors in the assumed values used in the computations. There are two columns for each tabulated value of latitude. The first gives the latitude factor, f, which is the error in minutes of latitude for a one-minute error of longitude. The second gives the longitude factor, F, which is the error in minutes of longitude for a one-minute error of latitude. In each case, the total error is the factor multiplied by the number of minutes error in the assumed value. Although the factors were originally intended for use in correcting ex-meridian altitudes and time-sight longitudes, they have other uses which may suggest themselves.

The azimuth angle used for entering the table can be measured from *either* the north or south, through 90°; or it may be measured from the elevated pole, through 180°. If the celestial body is in the southeast (090°–180°) or northwest (270°–360°) quadrant, the f correction is applied to the northward if the correct longitude is east of that used in the solution, and to the southward if the correct longitude is west of that used; while the F correction is applied to the eastward if the correct latitude is north of that used in the solution, and to the westward if the correct latitude is south of that used. If the body is in the northeast (000°–090°) or southwest (180°–270°) quadrant, the correction is applied in the opposite direction. These rules apply in both north and south latitude.

The table was computed by means of the formulas:

$$f = \cos L \tan Z = \frac{1}{\sec L \cot Z} = \frac{1}{F},$$

$$F = \sec L \cot Z = \frac{1}{\cos L \tan Z} = \frac{1}{f},$$

in which f is the tabulated latitude factor, L is the latitude, Z is the azimuth angle, and F is the tabulated longitude factor.

Table 27. Amplitudes.—This table lists amplitudes of celestial bodies at rising and setting. Enter with the declination of the body and the latitude of the observer. The value taken from the table is the amplitude when the *center* of the body is on the *celestial* horizon. For the sun, this occurs when the lower limb is a little more than half a diameter above the visible horizon. For the moon it occurs when the upper limb is about on the horizon. Use the prefix E if the body is rising, and W if it is setting; use the suffix N or S to agree with the declination of the body. Table 28 can be used with reversed sign to correct the tabluations to the values for the visible horizon. Use of table 27 is explained in article 720.

The table was computed by means of the following formula, derived by Napier's rules (art. 142):

$$\sin A = \sec L \sin d,$$

in which A is the amplitude, L is the latitude of the observer, and d is the declination of the celestial body.

Table 28. Correction of Amplitude as Observed on the Visible Horizon.—This table contains a correction to be applied to the amplitude observed when the center of a celestial body is on the visible horizon, to obtain the corresponding amplitude when the center of the body is on the celestial horizon. For the sun, a planet, or a star, apply the correction in the direction *away* from the elevated pole, thus *increasing* the *azimuth angle*. For the moon apply *half* the correction *toward* the elevated pole. This correction can be applied in the opposite direction to a value taken from table 27, to find the corresponding amplitude when the center of a celestial body is on the visible horizon. The table was computed for a height of eye of 41 feet. For other heights normally encountered, the error is too small to be of practical significance in ordinary navigation. Use of the table is explained in article 720.

The values in the table were determined by computing the azimuth angle when the center of the celestial body is on the visible horizon, converting this to amplitude, and determining the difference between this value and the corresponding value from table 27. Computation of azimuth angle was made for an altitude of (−)0°42′.0, determined as follows:

Dip at 41 feet height of eye	(−) 6′.2
Refraction at (−)6′.2 alt.	(−)35′.3
Irradiation of horizon	(−) 0′.6
Parallax (value for sun)	(+) 0′.1
	(−)42′.0.

Azimuth angle was computed by means of the formula:

$$\cos Z = \frac{\sin d - \sin h \sin L}{\cos h \cos L},$$

in which Z is the azimuth angle, d is the declination of the celestial body, h is the altitude (−0°42′.0), and L is the latitude of the observer.

Table 29. Altitude Factor.—In one minute of time from meridian transit the altitude of a celestial body changes by the amount shown in this table if the altitude is between 6° and 86°, the latitude is not more than 60°, and the declination is not more than 63°. The values taken from this table are used to enter table 30 for solving reduction to the meridian (ex-meridian) problems.

For upper transit, use the left-hand pages if the declination and latitude are of the same name (both north or both south) and the right-hand pages if of contrary name. For lower transit, use the values below the heavy lines on the last three contrary-name pages. When a factor is taken from this part of the table, the correction from table 30 is *subtracted* from the observed altitude to obtain the corresponding meridian altitude. All other corrections are added.

The table was computed by means of the formula:

$$a = 1''.9635 \cos L \cos d \csc (L \sim d),$$

in which a is the change of altitude in one minute from meridian transit (the tabulated value), L is the latitude of the observer, and d is the declination of the celestial body.

This formula can be used to compute values outside the limits of the table, but is not accurate if the altitude is greater than 86°.

Table 30. Change of Altitude in Given Time from Meridian Transit.—Enter this table with the altitude factor from table 29 and the meridian angle, in either arc or time units, and take out the difference between the altitude at the given time and the

altitude at meridian transit. Enter the table separately with whole numbers and tenths of a, interpolating for t if necessary, and add the two values to obtain the total difference. This total can be applied as a correction to observed altitude to obtain the corresponding meridian altitude, adding for upper transit and subtracting for lower transit.

The table was computed by means of the formula:

$$C = \frac{at^2}{60},$$

in which C is the tabulated difference to be used as a correction to observed altitude, in minutes of arc; a is the altitude factor from table 29, in seconds of arc; and t is the meridian angle, in minutes of time.

This formula should not be used for determining values beyond the limits of the table, unless reduced accuracy is acceptable.

Table 31. Natural Trigonometric Functions.—This table gives the values of natural sines, cosecants, tangents, cotangents, secants, and cosines of angles from 0° to 180°, at intervals of 1′. For angles between 0° and 45° use the column labels at the top and the minutes at the left; for angles between 45° and 90° use the column labels at the bottom and the minutes at the right; for angles between 90° and 135° use the column labels at the bottom and the minutes at the left; and for angles between 135° and 180° use the column labels at the top and the minutes at the right. These combinations are indicated by the arrows accompanying the figures representing the number of degrees. For angles between 180° and 360°, subtract 180° and proceed as indicated above to obtain the numerical values of the various functions.

Differences between consecutive entries are shown in the "Diff. 1′ " column to the right of each column of values of a trigonometric function, as an aid to interpolation. These differences are one-half line out of step with the numbers to which they apply, as in a critical table. Each difference applies to the values half a line above and half a line below. To determine the correction to apply to the value for the smaller entering angle, multiply the difference by the number of tenths of a minute $\left(\text{or } \frac{\text{seconds}}{60}\right)$ of the entering angle. Note whether the function is increasing or decreasing, and add or subtract the correction as appropriate, so that the interpolated value lies between the two values between which interpolation is made.

The logarithms of values given in this table are given in table 33. The trigonometric functions are explained in article 139.

Table 32. Logarithms of Numbers.—The first page of this table gives the complete common logarithm (characteristic and mantissa) of numbers 1 through 250. The succeeding pages give the mantissa only of the common logarithm of any number. Values are given for four significant digits of entering values, the first three being in the left-hand column, and the fourth at the heading of one of the other columns. Thus, the mantissa of a three-digit number is given in the column headed 0, on the line with the given number; while the mantissa of a four-digit number is given in the column headed by the fourth digit, on the line with the first three digits. As an example, the mantissa of 328 is 51587, while that of 3.284 is 51640. For additional digits, interpolation should be used. The difference between each tabulated mantissa and the next larger tabulated mantissa is given in the "d" column to the right of the smaller mantissa. This difference can be used to enter the appropriate proportional parts ("Prop. parts") auxiliary table to interpolate for the fifth digit of the given number. If an accuracy of more than five significant digits is to be preserved in a computation, a table of logarithms to additional decimal places should be used. For a number of one or two digits, use the first

page of the table or add zeros to make three digits. That is, the mantissa of 3, 30, and 300 is the same, 47712. Interpolation on the first page of the table is not recommended. The second part should be used for values not listed on the first page.

Additional information on the nature and use of logarithms is given in article 110.

Table 33. Logarithms of Trigonometric Functions.—This table gives the common logarithms (+10) of sines, cosecants, tangents, cotangents, secants, and cosines of angles from 0° to 180°, at intervals of 1′. For angles between 0° and 45° use the column labels at the top and the minutes at the left; for angles between 45° and 90° use the column labels at the bottom and the minutes at the right; for angles between 90° and 135° use the column labels at the bottom and the minutes at the left; and for angles between 135° and 180° use the column labels at the top and the minutes at the right. These combinations are indicated by the arrows accompanying the figures representing the number of degrees. For angles between 180° and 360°, subtract 180° and proceed as indicated above to obtain the numerical values of the various functions.

Differences between consecutive entries are shown in the "Diff. 1′ " columns as in table 31, except that one difference column is used for both sines and cosecants, another for both tangents and cotangents, and a third for both secants and cosines. These differences, given as an aid to interpolation, are one-half line out of step with the numbers to which they apply, as in a critical table. Each difference applies to the values half a line above and half a line below. To determine the correction to apply to the value for the smaller entering angle, multiply the difference by the number of tenths of a minute $\left(\text{or } \frac{\text{seconds}}{60}\right)$ of the entering angle. Note whether the function is increasing or decreasing, and add or subtract the correction as appropriate, so that the interpolated value lies between the two values between which interpolation is made.

Natural trigonometric functions are given in table 31. The trigonometric functions, both natural and logarithmic, are explained in article 139.

Table 34. Haversines.—This table lists the common logarithms (+10) of haversines, and natural haversines, of angles from 0° to 360°, at intervals of 1′. For angles between 0° and 180° use the degrees as given at the tops of the columns and the minutes at the left; for angles between 180° and 360° use the degrees as given at the bottoms of the columns and the minutes at the right.

A haversine is half of a versed sine:

$$\text{hav } A = \tfrac{1}{2} \text{ ver } A = \tfrac{1}{2}(1 - \cos A) = \sin^2 \tfrac{1}{2} A.$$

It is further discussed in article 139.

Table 35. The Ageton Method.—The late Rear Admiral Arthur A. Ageton, USN, devised this method while serving in the grade of lieutenant. It was first published in 1931 as H.O. Pub. No. 211, *Dead Reckoning Altitude and Azimuth Table.*

The table is designed for the solution of the divided astronomical triangle with all formulas in terms of secants and cosecants. The table gives five-place log cosecants (labeled A) and log secants (labeled B), both multipled by 100,000 to eliminate the characteristic and decimal. These values are given in parallel columns for each 0′.5 of angle from 0° to 180°. The method can be used for solution from the dead reckoning or any other assumed position. The method is intended for use without interpolation. However, when the quantity K used in the solution or the meridian angle approaches 90°, the solution accuracy is significantly reduced. When the value of K is found to lie within the limits of 87°30′ and 92°30′, the maximum error in computed altitude without interpolation is about 30′. When interpolation is neglected outside these limits, the maximum error is about 6′. The interpolation of the log secant (B) of R, the auxil-

iary part used to divide the oblique spherical triangle into two right spherical triangles, from the log cosecant (A) of R *alone* reduces the maximum error in altitude to about 2′.0 when K is 90° and to about 0′.8 when K is 80°. When K is between 82° and 98°, it is good practice to either discard the sight or to interpolate the log secant (B) of R from the log cosecant (A) of R. Use of the table is explained in articles 718 and 1012.

Table 36. Time Zones, Zone Descriptions, and Suffixes.—The zone description and the single letter of the alphabet designating a time zone and sometimes used as a suffix to zone time for all time zones are given in this table.

Table 37. Natural and Numerical Chart Scales.—This table gives the numerical scale equivalents for various natural or fractional chart scales.

The scale of a chart is the ratio of a given distance on the chart to the actual distance which it represents on the earth. The scale may be expressed as a simple ratio or fraction, the natural scale. For example, 1:80,000 or $\frac{1}{80,000}$ means that one unit (such as an inch) on the chart represents 80,000 of the same unit on the surface of the earth. Or the scale may be expressed as a statement of that distance on the earth shown as one unit (usually an inch) on the chart, or vice versa. This is the numerical scale.

The table was computed using 72,913.39 inches per nautical mile and 63,360 inches per statute mile.

Correction to latitude = f × error in longitude | Correction to longitude = F × error in latitude

TABLE 26

Latitude and Longitude Factors

f, the change of latitude for a unit change in longitude

F, the change of longitude for a unit change in latitude

Azimuth angle	Latitude 60° f	60° F	62° f	62° F	64° f	64° F	66° f	66° F	68° f	68° F	Azimuth angle

For the **sun**, a **planet**, or a **star**, apply the correction to the observed amplitude in the direction **away** from the elevated pole. For the **moon** apply **half** the correction **toward** the elevated pole.

TABLE 29

Altitude Factor

a, the change of altitude in one minute from meridian transit; used for entering table 30

Declination **same** name as latitude, **upper** transit: **add** correction to observed altitude

Arithmetic

101. Definitions.—Arithmetic is that branch of mathematics dealing with computation by numbers. The principal processes involved are addition, subtraction, multiplication, and division. A number consisting of a single symbol (1, 2, 3, etc.) is a **digit.** Any number that can be stated or indicated, however large or small, is called a **finite** number; one too large to be stated or indicated is called an **infinite** number; and one too small to be stated or indicated is called in **infinitesimal** number.

The **sign** of a number is the indication of whether it is positive (+) or negative (−). This may sometimes be indicated in another way. Thus, latitude is usually indicated as *north* (N) or *south* (S), but if north is considered positive, south is then negative with respect to north. In navigation, the north or south designation of latitude and declination is often called the "name" of the latitude or declination. A **positive number** is one having a positive sign (+); a **negative number** is one having a negative sign (−). The **absolute value** of a number is that number without regard to sign. Thus, the absolute value of both (+)8 and (−)8 is 8. Generally, a number without a sign can be considered positive.

102. Expressing numbers.—In navigation, fractions are usually expressed as decimals. Thus, ¼ is expressed as 0.25 and ⅓ as 0.33. To determine the decimal equivalent of a fraction, divide the **numerator** (the number above the line) by the **denominator** (the number below the line). When a decimal is less than 1, as in the examples above, it is good practice to show the zero at the left of the decimal point (0.25, not .25).

A number should not be expressed to a greater precision than justified. The precision of a decimal is indicated by the number of digits shown to the right of the decimal point. Thus, the expression "14 miles" indicates a precision to the nearest whole mile, or any value between 13.5 and 14.5 miles. The expression "14.0 miles" indicates a precision of a tenth of a mile, or any value between 13.95 and 14.05 miles.

In a number without a decimal there is sometimes doubt as to the degree of precision indicated. For example, the number 186,000 may indicate a precision to three, four, five, or six places. This ambiguity is sometimes avoided by expressing numbers as powers of 10 (art. 108). Thus, 18.6×10^4 ($18.6\times10{,}000$) indicates a precision to the nearest thousand (three places), 18.60×10^4 to the nearest hundred (four places), 18.600×10^4 to the nearest ten (five places), and 18.6000×10^4 to the nearest unit (six places). The position of the decimal is not important if the correct power of 10 is given. For example, 18.6×10^4 is the same as 1.86×10^5, 186×10^3, etc.

The small number above and to the right of 10 (the **exponent**) indicates the number of places the decimal point is to be moved to the *right*. If the exponent is negative, it indicates a reciprocal, and the decimal point is moved to the *left*. Thus, 1.86×10^{-8} $=0.00000186$. This system is sometimes used to avoid long numbers.

Another way of indicating degree of precision is to state the number of **significant digits.** These are the digits in a number, excluding zeros at the left and sometimes those at the right. Thus, 1,325, 1,001, 1.408, 0.00005926, 625.0, and 0.04000 have four significant digits each. But in the number 312,600 there may be four, five, or six sig-

nificant digits. Any doubt may be removed by expressing the number times a power of 10, as explained above.

If there are no more significant digits, regardless of how far a computation is carried, this may be indicated by use of the word "exactly." Thus, $12 \div 4 = 3$ exactly, and one nautical mile = 1,852 meters exactly; but $12 \div 7 = 1.7$ approximately, the word "approximately" indicating that additional decimal places might be computed. Another way of indicating an approximate relationship is by placing a positive or negative sign after the number. Thus, $12 \div 7 = 1.7+$, and $11 \div 7 = 1.6-$. This system has the advantage of showing whether the approximation is too great or too small.

In any arithmetical computation the answer is no more accurate than the least precise value used. Thus, if it is desired to add 16.4 and 1.88, the answer might be given as 18.28, but since the first term might be anything from 16.35 to 16.45, the answer is anything from 18.23 to 18.33. Hence, to retain the second decimal place in the answer is to give a false indication of accuracy, for the number 18.28 indicates a value between 18.275 and 18.285. However, additional places are sometimes retained until the end of a computation to avoid an accumulation of small errors due to rounding off (art. 104). In marine navigation it is customary to give most values to a precision of 0.1, even though some uncertainty may exist as to the accuracy of the last place. Examples are the dip and refraction corrections of sextant altitudes (arts. 805, 806).

In general, a value obtained by interpolation in a table should not be expressed to more decimal places than given in the table.

103. Precision and accuracy.—The word "precision" as used above is not the same as "accuracy," although the two are sometimes confused. A quantity may be expressed to a greater precision than is justified by the accuracy of the information from which the quantity is derived. For instance, if a ship steams one mile in 3^m21^s, its speed is $60^m \div 3^m21^s = 60 \div 3.35 = 17.910447761194$ knots, approximately. The division can be carried to as many places as desired, but if the time is measured only to the nearest second, the speed is accurate only to one decimal place in this example, because an error of 0.5 second introduces an error of more than 0.05 knot in the speed. Hence, the additional places are meaningless and possibly misleading, unless more accurate time is available. In general, it is not good practice to state a quantity to greater precision than justified by its accuracy. However, in marine navigation the accuracy of information is often unknown, and it is customary to give positions to a precision of 0′.1 of latitude and longitude, although they *may* not be accurate even to the nearest whole minute.

The **absolute precision** of a number is indicated by its number of decimal places; its **relative precision** by its number of significant digits. Although this is an indication of precision, it may also be a measure of accuracy, and the expressions **absolute accuracy** and **relative accuracy** used. However, the term "accuracy" should not be used when "precision" only is intended. Thus, the values 186,000 and 0.00000186 may each have three significant digits, or "be correct to three digits," although the first value may be accurate ("absolute accuracy") only to the nearest 1,000, and the second to the nearest 0.00000001. If the numbers are accurate to the number of significant digits shown, each has an error ("relative accuracy") of less than "one part in 186."

Unless all numbers are exact, doubt exists as to the accuracy of the last digit in a computation. Thus, $12.3+9.4+4.6=26.3$. But if the three terms to be added have been rounded off from 12.26, 9.38, and 4.57, the correct answer is 26.2, obtained by rounding off the answer of 26.21 found by retaining the second decimal place until the end. It is good practice to work with one more place than needed in the answer, when the information is available. In computations involving a large number of terms, or

if great accuracy is desired, it is sometimes advisable to retain two or more additional places until the end.

104. Rounding off.—In rounding off numbers to the number of places desired, one should take the nearest value. Thus, the number 6.5049 is rounded to 6.505, 6.50, 6.5, or 7, depending upon the number of places desired. If the number to be rounded off ends in 5, the nearer *even* number is taken. Thus, 1.55 and 1.65 are both rounded to 1.6. Likewise, 12.750 is rounded to 12.8 if only one decimal place is desired. However, 12.749 is rounded to 12.7. That is, 12.749 is not first rounded to 12.75 and then to 12.8, but the entire number is rounded in one operation. When a number ends in 5, the computation can sometimes be carried to additional places to determine whether the correct value is more or less than 5.

105. Reciprocals.—The reciprocal of a number is 1 divided by that number. The reciprocal of a fraction is obtained by interchanging the numerator and denominator. Thus, the reciprocal of $\frac{3}{5}$ is $\frac{5}{3}$. A whole number may be considered a fraction with 1 as the denominator. Thus, 54 is the same as $\frac{54}{1}$, and its reciprocal is $\frac{1}{54}$. Division by a number produces the same result as multiplying by its reciprocal, or vice versa. Thus, $12 \div 2 = 12 \times \frac{1}{2} = 6$, and $12 \times 2 = 12 \div \frac{1}{2} = 24$.

106. Addition.—When two or more numbers are to be added, it is generally most convenient to write them in a column, with the decimal points in line. Thus, if 31.2, 0.8874, and 168.14 are to be added, this may be indicated by means of the addition sign (+): $31.2 + 0.8874 + 168.14 = 200.2$. But the addition can be performed more conveniently by arranging the numbers as follows:

$$\begin{array}{r} 31.2 \\ 0.8874 \\ 168.14 \\ \hline 200.2. \end{array}$$

The answer is given only to the first decimal place, because the answer is no more accurate than the least precise number among those to be added, as indicated previously. Often it is preferable to state all numbers in a problem to the same precision before starting the addition, although this may introduce a small error, as indicated in article 103:

$$\begin{array}{r} 31.2 \\ 0.9 \\ 168.1 \\ \hline 200.2. \end{array}$$

If there are no decimals, the last digit to the right is aligned:

$$\begin{array}{r} 166 \\ 2 \\ 96{,}758 \\ \hline 96{,}926. \end{array}$$

Numbers to be added should be given to the same absolute accuracy, when available, to avoid a false impression of accuracy in the result. Consider the following:

$$\begin{array}{r} 186{,}000 \\ 71{,}832 \\ 9{,}614 \\ 728 \\ \hline 268{,}174. \end{array}$$

The answer would imply an accuracy to six places. If the first number given is accurate to only three places, or to the nearest 1,000, the answer is not more accurate, and hence the answer should be given as 268,000. Approximately the same answer would be obtained by rounding off at the start:

186,000
72,000
10,000
1,000
269,000.

If numbers are **added arithmetically,** their absolute values are added without regard to signs; but if they are **added algebraically,** due regard is given to signs. If two numbers to be added algebraically have the same sign, their absolute values are added and given their common sign. If two numbers to be added algebraically have unlike signs, the smaller absolute value is subtracted from the larger, and the sign of the value having the larger absolute value is given to the result. Thus, if +8 and −7 are added arithmetically, the answer is 15, but if they are added algebraically, the answer is +1.

An answer obtained by addition is called a **sum.**

107. Subtraction is the inverse of addition. Stated differently, the *addition* of a *negative* number is the same as the *subtraction* of a *positive* number. That is, if a number is to be subtracted from another, the sign (+ or −) of the **subtrahend** (the number to be subtracted) is reversed and the result added algebraically to the **minuend** (the number from which the subtrahend is to be subtracted). Thus, 6−4=2. This may be written +6−(+4)=+2, which yields the same result as +6+ (−4). For solution, larger numbers are often conveniently arranged in a column with decimal points in a vertical column, as in addition. Thus, 3,728.41−1,861.16 may be written:

(+)3,728.41
(+)1,861.16 (subtract)
(+)1,867.25

This is the same as:

(+)3,728.41
(−)1,861.16 (add algebraically)
(+)1,867.25.

The rule of sign reversal applies likewise to negative numbers. Thus, if −3 is to be *subtracted* from +5, this may be written +5−(−3)=5+3=8.

In the algebraic addition of two numbers of opposite sign (numerical subtraction), the smaller number is subtracted from the larger and the result is given the sign of the larger number. Thus, +7−4=+3, and −7+4=−3, which is the same as +4 −7=−3.

In navigation, numbers to be numerically subtracted are usually marked (−), and those to be numerically added are marked (+) or the sign is not indicated. However, when a sign is part of a designation, and the reverse process is to be used, the word "reversed" (rev.) is written after the number. Thus, if GMT is known and ZT in the (+)5 zone is to be found (by subtraction), the problem may be written:

GMT 1754
ZD (+)5 (rev.)
ZT 1254.

The symbol ∼ indicates that an absolute difference is required without regard to sign of the *answer*. Thus, 28∼13=15, and 13∼28=15. In both of these solutions 13

and 28 are positive and 15 is an absolute value without sign. If the signs or names of both numbers are the same, either positive or negative, the smaller is subtracted from the larger, but if they are of opposite sign or name, they are numerically added. Thus, $(+)16\sim(+)21=5$ and $(-)16\sim(-)21=5$, but $(+)16\sim(-)21=37$ and $(-)16\sim(+)21=37$. Similarly, the difference of latitude between 15°N and 20°N, or between 15°S and 20°S, is 5°, but the difference of latitude between 15°N and 20°S, or between 15°S and 20°N, is 35°. If motion from one latitude to another is involved, the difference may be given a sign to indicate the direction of travel, or the location of one place with respect to another. Thus, if B is 50 miles west of A, and C is 125 miles west of A, B and C are 75 miles apart regardless of the direction of travel. However, B is 75 miles *east* of C, and C is 75 miles *west* of B. When direction is indicated, an algebraic difference is given, rather than an absolute difference, and the symbol $\sim$ is not appropriate.

It is sometimes desirable to consider all addition and subtraction problems as addition, with negative signs (−) given before those numbers to be subtracted, so that there can be no question of which process is intended. The words "add" and "subtract" may be used instead of signs. In navigation, "names" (usually north, south, east, and west) are often used, and the relationship involved in a certain problem may need to be understood to determine whether to add or subtract. Thus, LHA=GHA−λ(west) and LHA=GHA+λ(east). This is the same as saying LHA=GHA−λ if west longitude is considered positive, for in this case, LHA=GHA−(−λ) or LHA=GHA+λ in east longitude, the same as before.

If numbers are **subtracted arithmetically,** they are subtracted without regard to sign; but if they are **subtracted algebraically,** positive (+) numbers are *subtracted* and negative (−) numbers are *added.*

An answer obtained by subtraction is called a **difference.**

108. Multiplication may be indicated by the multiplication sign (×), as 154×28 =4,312. For solution, the problem is conveniently arranged thus:

$$\begin{array}{r} 154 \\ (\times)\ 28 \\ \hline 1232 \\ 308 \\ \hline 4312. \end{array}$$

Either number may be given first, but it is generally more convenient to perform the multiplication if the larger number is placed on top, as shown. In this problem, 154 is first multiplied by 8 and then by 2. The second answer is placed under the first, but set one **place** to the left, so that the right-hand digit is directly below the 2 of the multiplier. These steps might be reversed, multiplication by 2 being performed first. This procedure is sometimes used in estimating.

When one number is placed below another for multiplication, as shown above, it is usually best to align the right-hand digits without regard for the position of the decimal point. The number of decimal places in the answer is the sum of the decimal places in the **multiplicand** (the number to be multiplied) and the **multiplier** (the second number):

$$\begin{array}{r} 163.27 \\ (\times)\ 263.9 \\ \hline 146943 \\ 48981 \\ 97962 \\ 32654 \\ \hline 43086.953. \end{array}$$

However, when a number ends in one or more zeros, these may be ignored until the end and then added on to the number:

$$\begin{array}{r} 1924 \\ (\times)1800 \\ \hline 15392 \\ 1924 \\ \hline 3463200. \end{array}$$

This is also true if both multiplicand and multiplier end in zeros:

$$\begin{array}{r} 1924000 \\ (\times)1800 \\ \hline 15392 \\ 1924 \\ \hline 3463200000. \end{array}$$

When negative values are to be multiplied, the sign of the answer is positive if an *even* number of negative signs appear, and negative if there are an *odd* number. Thus, $2\times3=6$, $2\times(-3)=-6$, $-2\times3=-6$, $-2\times(-3)=(+)6$. Also, $2\times3\times8\times(-2)\times5=-480$, $2\times(-3)\times8\times(-2)\times5=480$, $2\times(-3)\times(-8)\times(-2)\times5=-480$, $2\times(-3)\times(-8)\times(-2)\times(-5)=480$, and $(-2)\times(-3)\times(-8)\times(-2)\times(-5)=-480$.

An answer obtained by multiplication is called a **product.** Any number multiplied by 1 is the number itself. Thus, $125\times1=125$. Any number multiplied by 0 is 0. Thus, $125\times0=0$ and $1\times0=0$.

To multiply a number by itself is to **square** the number. This may be indicated by the **exponent** 2 placed to the right of the number and above the line as a **superior.** Thus, 15×15 may be written 15^2. Similarly, $15\times15\times15=15^3$, and $15\times15\times15\times15=15^4$, etc. The exponent (2, 3, 4, etc.) indicates the **power** to which a number is to be **raised,** or how many times the number is to be used in multiplication. The expression 15^2 is usually read "15 squared," 15^3 is read "15 cubed" or "15 to the third power," 15^4 (or higher power) is read "15 to the fourth (or higher) power." The answer obtained by **raising to a power** is called the "square," "cube," etc., or the ". . . power" of the number. Thus, 225 is the "square of 15," 3,375 is the "cube of 15" or the "third power of 15," etc. The zero power of any number except zero (if zero is considered a number) is 1. The zero power of zero is zero. Thus, $15^0=1$ and $0^0=0$.

Parentheses may be used to eliminate doubt as to what part of an expression is to be raised to a power. Thus, -3^2 may mean either $-(3\times3)=-9$ or $-3\times-3=(+)9$. To remove the ambiguity, the expression may be written $-(3)^2$ if the first meaning is intended, and $(-3)^2$ if the second meaning is intended.

109. Division is the inverse of multiplication. It may be indicated by the division sign ($\div$), as $376\div21=18$ approximately; or by placing the number to be divided, called the **dividend** (376), over the other number, called the **divisor** (21), as $\frac{376}{21}=18$ approximately. The expression $\frac{376}{21}$ may be written 376/21 with the same meaning. Such a problem is conveniently arranged for solution as follows:

$$\begin{array}{r|l} & 17 \\ 21 & 376 \\ & 21 \\ \hline & 166 \\ & 147 \\ \hline & 19. \end{array}$$

Since the **remainder** is 19, or more than half of the divisor (21), the answer is 18 to the nearest whole number.

An answer obtained by division is called a **quotient.** Any number divided by 1 is the number itself. Thus, $65 \div 1 = 65$. A number cannot be divided by 0.

If the numbers involved are accurate only to the number of places given, the answer should not be carried to additional places. However, if the numbers are exact, the answer might be carried to as many decimal places as desired. Thus, $374 \div 21 = 17.809523809523809523809523809523809523$ . . . . When a series of digits repeat themselves with the same remainder, as 809523 (with remainder 17) in the example given above, an exact answer will not be obtained regardless of the number of places to which the division is carried. The series of dots (. . .) indicates a **repeating decimal.** In a nonrepeating decimal, a plus sign (+) may be given to indicate a remainder, and a minus sign (−) to indicate that the last digit has been rounded to the next higher value. Thus, 18.68761 may be written 18.6876+ or 18.688−. If the last digit given is rounded off, the word "approximately" may be used instead of dots or a plus or minus sign.

If the divisor is a whole number, the decimal point in the quotient is directly above that of the dividend when the work form shown above is used. Thus, in the example given above, if the dividend had been 37.6 instead of 376, the quotient would have been 1.8 approximately. If the divisor is a decimal, both it and the dividend are multiplied by the power of 10 having an exponent equal to the number of decimal places in the divisor, and the division is then carried out as explained above. Thus, if there are two decimal places in the divisor, both divisor and dividend are multiplied by $10^2 = 100$. This is done by moving the decimal to the right until the divisor is a whole number. If necessary, zeros are added to the dividend. Thus, if 3.7 is to be divided by 2.11, both quantities are first multiplied by 10^2, and 370 is divided by 211. This is usually performed as follows:

```
          1.75
2/11 ) 3/70.00
       211
       1590
       1477
        1130
        1055
          75.
```

If *both* the dividend and divisor are positive, or if *both* are negative, the quotient is positive; but if *either* is negative, the quotient is negative. Thus, $6 \div 3 = 2$, $(-6) \div (-3) = +2$, $(-6) \div 3 = -2$, and $6 \div (-3) = -2$.

The **square root** of a number is that number which, multiplied by itself, equals the given number. Thus, $15 \times 15 = 15^2 = 225$, and $\sqrt{225} = 225^{1/2} = 15$. Either the symbol $\sqrt{\ }$, called the **radical sign,** or the exponent ½ indicates square root. Also, $\sqrt[3]{\ }$, or ⅓ as an exponent, indicates **cube root.** Fourth, fifth, or any root is indicated similarly, using the appropriate number. Nearly any arithmetic book explains the process of extracting roots, but this process is most easily performed by table, logarithms (art. 112), or slide rule (art. 115). If no other means are available, it can be done by trial and error. The process of finding a root of a number is called **extracting a root.**

110. Logarithms ("logs") provide an easy way to multiply, divide, raise numbers to powers, and extract roots. The logarithm of a number is the power to which a fixed number, called the base, must be raised to produce the value to which the logarithm corresponds. The base of **common logarithms,** (given in tables 32 and 33) is 10. Hence, since $10^{1.8} = 63$ approximately, 1.8 is the logarithm, approximately, of 63 to the base

10. In table 32 logarithms of numbers are given to five decimal **places.** This is sufficient for most purposes of the navigator. For greater precision, a table having additional places should be used. In general, the number of *significant digits* which are correct in an answer obtained by logarithms is the same as the number of *places* in the logarithms used.

A logarithm is composed of two parts. That part to the left of the decimal point is called the **characteristic.** That part to the right of the decimal point is called the **mantissa.** The principal advantage of using 10 as the base is that any given combination of digits has the same mantissa regardless of the position of the decimal point. Hence, only the mantissa is given in the main tabulation of table 32. Thus, the logarithm (mantissa) of 2,374 is given as 37548. This is correct for 2,374,000,000; 2,374; 23.74; 2.374; 0.2374; 0.000002374; or for any other position of the decimal point.

The position of the decimal point determines the characteristic, which is not affected by the actual digits involved. The characteristic of a whole number is one less than the number of digits. The characteristic of a **mixed decimal** (one greater than 1) is one less than the number of digits to the left of the decimal point. Thus, in the example given above, the characteristic of the logarithm of 2,374,000,000 is 9; that of 2,374 is 3; that of 23.74 is 1; and that of 2.374 is 0. The complete logarithms of these numbers are:

$$\begin{aligned}\log 2{,}374{,}000{,}000 &= 9.37548\\ \log 2{,}374 &= 3.37548\\ \log 23.74 &= 1.37548\\ \log 2.374 &= 0.37548.\end{aligned}$$

Since the mantissa of the logarithm of any multiple of ten is zero, the main table starts with 1,000. This can be considered 100, 10, 1, etc. Since the mantissa of these logarithms is zero, the logarithms consist of the characteristic only, and are whole numbers. Hence, the logarithm of 1 is 0 (0.00000), that of 10 is 1 (1.00000), that of 100 is 2 (2.00000), that of 1,000 is 3 (3.00000), etc.

The characteristic of the logarithm of a number less than 1 is negative. However, it is usually more conveniently indicated in a positive form, as follows: the characteristic is found by subtracting the number of zeros immediately to the right of the decimal point from 9 (or 19, 29, etc.) and following this by -10 (or -20, -30, etc.). Thus, the characteristic of the logarithm of 0.2374 is $9-10$; that of 0.000002374 is $4-10$; and that of 0.000000000002374 is $8-20$. The complete logarithms of these numbers are:

$$\begin{aligned}\log 0.2374 &= 9.37548-10\\ \log 0.000002374 &= 4.37548-10\\ \log 0.000000000002374 &= 8.37548-20.\end{aligned}$$

When there is no question of the meaning, the -10 may be omitted. This is usually done when using logarithms of trigonometric functions, as shown in table 33. Thus, if there is no reasonable possibility of confusion, the logarithm of 0.2374 may be written 9.37548.

Occasionally, the logarithm of a number less than 1 is shown by giving the negative characteristic with a minus sign above it (since only the characteristic is negative, the mantissa being positive). Thus, the logarithms of the numbers given above might be shown thus:

$$\begin{aligned}\log 0.2374 &= \bar{1}.37548\\ \log 0.000002374 &= \bar{6}.37548\\ \log 0.000000000002374 &= \bar{12}.37548.\end{aligned}$$

In each case, the negative characteristic is one *more* than the number of zeros immediately to the right of the decimal point.

There is no real logarithm of 0, since there is no *finite* power to which *any* number can be raised to produce 0. As numbers approach 0, their logarithms approach negative infinity.

To find the number corresponding to a given logarithm, called finding the **antilogarithm** ("antilog"), enter the table with the mantissa of the given logarithm and determine the corresponding number, interpolating if necessary. Locate the position of the decimal point by means of the characteristic of the logarithm, in accordance with the rules given above.

111. Multiplication by logarithms.—To *multiply* one number by another, *add* their logarithms and find the antilogarithm of the sum. Thus, to multiply 1,635.8 by 0.0362 by logarithms:

$$\begin{aligned} \log\ 1635.8 &= 3.21373 \\ \log\ 0.0362 &= \underline{8.55871-10} \quad \text{(add)} \\ \log\ 59.216 &= 11.77244-10 \text{ or } 1.77244. \end{aligned}$$

Thus, $1{,}635.8 \times 0.0362 = 59.216$. In navigation it is customary to use a slightly modified form, and to the omit the -10 where there is no reasonable possibility of confusion, as follows:

$$\begin{array}{rl} 1635.8 & \log\ 3.21373 \\ 0.0362 & \log\ \underline{8.55871} \\ 59.216 & \log\ 1.77244. \end{array}$$

To *raise a number to a power*, multiply the logarithm of that number by the power indicated, and find the antilogarithm of the product. Thus, to find 13.156^3 by logarithms, using the navigational form:

$$\begin{array}{rl} 13.156 & \log\ 1.11913 \\ & \times\ \underline{\qquad 3} \quad \text{(multiply)} \\ 2277.2 & \log\ 3.35739. \end{array}$$

112. Division by logarithms.—To *divide* one number by another, subtract the logarithm of the divisor from that of the dividend, and find the antilogarithm of the remainder. Thus, to find $0.4637 \div 28.03$ by logarithms, using the navigational form:

$$\begin{array}{rrl} 0.4637 & \log & 9.66624 \\ 28.03 & \log\ (-) & \underline{1.44762} \quad \text{(subtract)} \\ 0.016543 & \log & 8.21862. \end{array}$$

It is sometimes necessary to modify the first logarithm before the subtraction can be made. This would occur in the example given above, for instance, if the divisor and dividend were reversed, so that the problem became $28.03 \div 0.4637$. In this case $10-10$ would be added to the logarithm of the dividend, becoming $11.44762-10$:

$$\begin{array}{rrl} 28.03 & \log & 11.44762-10 \\ 0.4637 & \log\ (-) & \underline{9.66624-10} \\ 60.448 & \log & 1.78138. \end{array}$$

One experienced in the use of logarithms usually carries this change mentally, without showing it in his work form:

$$\begin{array}{rrl} 28.03 & \log & 1.44762 \\ 0.4637 & \log\ (-) & \underline{9.66624} \\ 60.448 & \log & 1.78138. \end{array}$$

Any number can be added to the characteristic as long as that same number is also subtracted. Conversely, any number can be subtracted from the characteristic as long as that same number is also added.

To *extract a root* of a number, divide the logarithm of that number by the root indicated, and find the antilogarithm of the quotient. Thus, to find $\sqrt{7}$ by logarithms:

$$\begin{array}{rl} 7 & \log \overline{0.84510}\ (\div 2) \\ 2.6458 & \log \overline{0.42255}. \end{array}$$

To divide a negative logarithm by the root indicated, first modify the logarithm so that the quotient will have a -10. Thus, to find $\sqrt[3]{0.7}$ by logarithms:

$$\begin{array}{rl} 0.7 & \log \overline{29.84510-30}\ (\div 3) \\ 0.88792 & \log \overline{\ 9.94837-10} \end{array}$$

or, carrying the -30 and -10 mentally,

$$\begin{array}{rl} 0.7 & \log \overline{29.84510}\ (\div 3) \\ 0.88792 & \log \overline{\ 9.94837}. \end{array}$$

113. Cologarithms.—The **cologarithm** ("colog") of a number is the value obtained by subtracting the logarithm of that number from zero, usually in the form $10-10$. Thus, the logarithm of 18.615 is 1.26987. The cologarithm is:

$$\begin{array}{r} 10.00000-10 \\ (-)1.26987 \\ \hline 8.73013-10. \end{array}$$

Similarly, the logarithm of 0.0018615 is $7.26987-10$, and its cologarithm is:

$$\begin{array}{r} 10.00000-10 \\ (-)7.26987-10 \\ \hline 2.73013. \end{array}$$

The *cologarithm* of a number is the *logarithm* of the reciprocal of that number. Thus, the cologarithm of 2 is the logarithm of ½. Since division by a number is the same as multiplication by its reciprocal, the use of cologarithms permits division problems to be converted to problems of multiplication, eliminating the need for subtraction of logarithms. This is particularly useful when both multiplication and division are involved in the same problem. Thus, to find $\dfrac{92.732\times 0.0137\times 724.3}{0.516\times 3941.1}$ by logarithms, one might *add* the logarithms of the three numbers in the numerator, and *subtract* the logarithms of the two numbers in the denominator. If cologarithms are used for the numbers in the denominator, all logarithmic values are added. Thus, the solution might be made as follows:

92.732	log 1.96723
0.0137	log 8.13672
724.3	log 2.85992
0.516	log 9.71265 colog 0.28735
3941.1	log 3.59562 colog $\overline{6.40438}$
0.45248	log $\overline{9.65560}$.

114. Various kinds of logarithms.—As indicated above, **common logarithms** use 10 as the base. These are also called **Briggs' logarithms.** For some purposes, it is convenient to use 2.7182818 approximately (designated e) as the base for logarithms. These are called **natural logarithms** or **Naperian logarithms** ($\log_e$). Common logarithms are shown as $\log_{10}$ when the base might otherwise be in doubt.

Addition and subtraction logarithms are logarithms of the sum and difference of two numbers. They are used when the logarithms of two numbers to be added or subtracted are known, making it unnecessary to find the numbers themselves.

115. Slide rule.—A **slide rule** is a convenient device for making logarithmic solutions mechanically. There are many types and sizes of slide rule, some designed for specific purposes. The most common form consists of an outer "body" or "frame" with grooves to permit a "slide" to be moved back and forth between the two outer parts, so that any graduation of a scale on the slide can be brought opposite any graduation of a scale on the body. A cursor called an "indicator" or "runner" is provided to assist in aligning the desired graduations. In a **circular slide rule** the "slide" is an inner disk surrounded by a larger one, both pivoted at their common center. The scales of a slide rule are *logarithmic*. That is, they increase proportionally to the logarithms of the numbers indicated, rather than to the numbers themselves. This permits addition and subtraction of logarithms by simply measuring off part of the length of the slide from a graduated point on the body, or vice versa. Two or three complete scales within the length of the rule may be provided for finding squares, cubes, square roots, and cube roots.

Full instructions for use of a slide rule are provided with each rule, and given in some mathematical texts. Properly used, a slide rule can provide quick answers to many of the problems of navigation. However, its precision is usually limited to from two to four significant digits, and should not be used if greater precision is desired. It is frequently used to provide a quick, approximate check on answers obtained by a more laborious method.

Great care should be used in placing the decimal point in an answer obtained by slide rule, as the correct location often is not immediately apparent. Its position is usually determined by making a very rough mental solution. Thus, 2.93×8.3 is *about* $3 \times 8 = 24$. Hence, when the answer by slide rule is determined to be "243," it is known that the correct value is 24.3, not 2.43 or 243.

116. Mental arithmetic.—Many of the problems of the navigator can be solved mentally. The following are a few examples.

If the speed is a number divisible into 60 a whole number of times, distance problems can be solved by a simple relationship. Thus, at 10 knots a ship steams 1 mile in $\frac{60}{10} = 6$ minutes. At 12 knots it requires 5 minutes, at 15 knots 4 minutes, etc. As an example of the use of such a relationship, a vessel steaming at 12 knots travels 5.6 miles in 28 minutes, since $\frac{28}{5} = 5\frac{3}{5} = 5.6$, or 0.1 mile every half minute.

For relatively short distances, one nautical mile can be considered equal to 6,000 feet. Since one hour has 60 minutes, the speed in hundreds of feet per minute is equal to the speed in knots. Thus, a vessel steaming at 15 knots is moving at the rate of 1,500 feet per minute.

With respect to time, 6 minutes=0.1 hour, and 3 minutes=0.05 hour. Hence, a ship steaming at 13 knots travels 3.9 miles in 18 minutes (13×0.3), and 5.8 miles in 27 minutes (13×0.45).

In arc units, $6' = 0^\circ.1$ and $6'' = 0'.1$. This relationship is useful in rounding off values given in arc units. Thus, $17°23'44'' = 17°23'.7$ to the nearest $0'.1$, and $17^\circ.4$ to the nearest $0^\circ.1$. A thorough knowledge of the six multiplication table is valuable. The 15 multiplication table is also useful, since $15° = 1^h$. Hence, $16^h = 16 \times 15 = 240°$. This is particularly helpful in quick determination of zone description. Pencil and paper or a table should not be needed, for instance, to decide that a ship at sea in longitude $157°18'.4$ W is in the (+)10 zone.

It is also helpful to remember that $1°=4^m$ and $1'=4^s$. In converting the LMT of sunset to ZT, for instance, a quick mental solution can be made without reference to a table. Since this correction is usually desired only to the nearest whole minute, it is necessary only to multiply the longitude difference in degrees (to the nearest quarter degree) by four.

Vectors

117. Scalars and vector quantities.—A **scalar** is a quantity which has *magnitude* only; a **vector quantity** has both *magnitude* and *direction*. If a vessel is said to have a tank of 5,000 gallons capacity, the number 5,000 is a scalar. As used in this book, *speed* alone is considered a scalar, while *speed* and *direction* are considered to constitute *velocity*, a vector quantity. Thus, if a vessel is said to be steaming at 18 knots, without regard to direction, the number 18 is considered a scalar; but if the vessel is said to be steaming at 18 knots on course 157°, the combination of 18 knots and 157° constitutes a vector quantity. *Distance* and *direction* also constitute a vector quantity.

A *scalar* can be represented fully by a number. A *vector quantity* requires, in addition, an indication of direction. This is conveniently done graphically by means of a straight line, the length of which indicates the *magnitude*, and the direction of which indicates the *direction* of application of the magnitude. Such a line is called a **vector.** Since a straight line has two directions, reciprocals of each other, an arrowhead is placed along or at one end of a vector to indicate the direction represented, unless this is apparent or indicated in some other manner.

118. Addition and subtraction of vectors.—Two vectors can be *added* by *starting* the second at the *termination* (rather than the origin) of the first. A common navigational use of vectors is the dead reckoning plot of a vessel. Refer to figure 118. If a ship starts at *A* and steams 18 miles on course 090° and then 12 miles on course 060°, it arrives by dead reckoning at *C*. The line *AB* is the vector for the first run, and *BC* is the vector for the second. Point *C* is the position found by *adding* vectors *AB* and *BC*. The vector *AC*, in this case the *course and distance made good*, is the **resultant.** Its value, both in direction and amount, can be determined by measurement. Lines *AB*, *BC*, and *AC* are all **distance vectors. Velocity vectors** are used when determining the effect of, or allowing for, current, interconverting true and apparent wind, and solving relative motion problems.

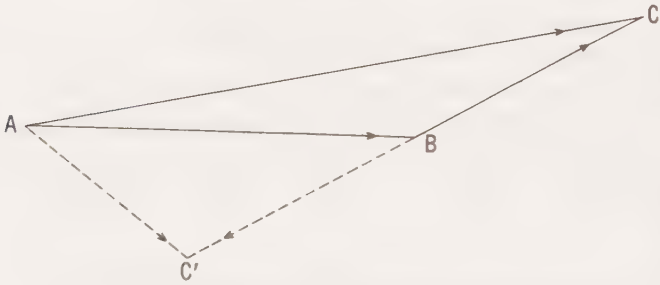

FIGURE 118.—Addition and subtraction of vectors.

The **reciprocal** of a vector has the same magnitude but opposite direction of the vector. To *subtract* a vector, *add* its reciprocal. This is indicated by the broken lines in figure 118, in which the vector *BC'* is drawn in the opposite direction to *BC*. In this case the resultant is *AC'*. Subtraction of vectors is involved in some current and wind problems.

Algebra

119. Definitions.—**Algebra** is that branch of mathematics dealing with computation by letters and symbols. It permits the mathematical statement of certain relationships between variables. When numbers are substituted for the letters, algebra becomes

arithmetic. Thus if $a=2b$, any value may be assigned to b, and a can be found by multiplying the assigned value by 2. Any statement of equality (as $a=2b$) is an **equation.** Any combination of numbers, letters, and symbols (as $2b$) is a **mathematical expression.**

120. Symbols.—As in arithmetic, plus (+) and minus (−) signs are used, and with the same meaning. Multiplication ($\times$) and division ($\div$) signs are seldom used. In algebra, $a\times b$ is usually written ab, or sometimes $a\cdot b$. For division $a\div b$ is usually written $\frac{a}{b}$ or a/b. The symbol $>$ means "greater than" and $<$ means "less than." Thus, $a>b$ means "a is greater than b," and $a\geqq b$ or $a\geq b$ means "a is equal to or greater than b."

The order of performing the operations indicated in an equation should be observed carefully. Consider the equation $a=b+cd-e/f$. If the equation is to be solved for a, the value cd should be determined by multiplication and e/f by division *before* the addition and subtraction, as each of these is to be considered a single quantity in making the addition and subtraction. Thus, if $cd=g$ and $e/f=h$, the formula can be written $a=b+g-h$.

If an equation including both multiplication and division between plus or minus signs is not carefully written, some doubt may arise as to which process to perform first. Thus, $a\div b\times c$ or $a/b\times c$ may be interpreted to mean either that a/b is to be multiplied by c or that a is to be divided by $b\times c$. Such an equation is better written ac/b if the first meaning is intended, or a/bc if the second meaning is intended. **Parentheses,** ( ), may be used for the same purpose or to indicate any group of quantitites that is to be considered a single quantity. Thus, $a(b+c)$ is an indication that the sum of b and c is to be multiplied by a. Similarly, $a+(b-c)^2$ indicates that c is first to be subtracted from b, and then the result is to be squared and the value thus obtained added to a. When an expression within parentheses is part of a larger expression which should also be in parentheses, **brackets,** [ ], are used in place of the outer parentheses. If yet another set is needed, **braces,** { }, are used.

A quantity written $\sqrt{3}\ ab$ is better written $ab\ \sqrt{3}$ to remove any suggestion that the square root of $3ab$ is to be found.

121. Addition and subtraction.—A plus sign before an expression in parentheses means that each term retains its sign as given. Thus, $a+(b+c-d)$ is the same as $a+b+c-d$. A minus sign preceding the parentheses means that each sign within the parentheses is to be reversed. For example, $a-(b+c-d)=a-b-c+d$.

In any equation involving addition and subtraction, similar terms can be combined. Thus, $a+b+c+b-2c-d=a+2b-c-d$. Also, $a+3ab+a^2-b-ab=a+2ab+a^2-b$. That is, to be combined, the terms must be truly alike, for a cannot be combined with ab, or with a^2.

Equal quantities can be added to or subtracted from both members of an equation without disturbing the equality. Thus, if $a=b$, $a+2=b+2$, or $a+x=b+x$. If $x=y$, then $a+x=b+y$.

122. Multiplication and division.—When an expression in parentheses is to be multiplied by a quantity outside the parentheses, each quantity separated by a plus or minus sign within the parentheses should be multiplied separately. Thus, $a(b+cd-e/f)$ may be written $ab+acd-ae/f$. Any quantity appearing in *every* term of one member of an equation can be separated out by **factoring,** or dividing each term by the common quantity. Thus, if $a=bc+\frac{bd}{e}-b^2+b$, the equation may be written $a=b\left(c+\frac{d}{e}-b+1\right)$.

Note that $\frac{b}{b}=1$ and $\frac{b^2}{b}=b$. This is the inverse of multiplication: $a\times 1=a$, but $a\times a=a^2$. Also, $a^2\times a^3=a^5$; and $\frac{a^7}{a^2}=a^5$. Thus, in multiplying a power of a number by a power of the same number, the powers are added, or, stated mathematically, $a^m\times a^n=a^{m+n}$. In division, $\frac{a^m}{a^n}=a^{m-n}$, or the exponents are subtracted. If n is greater than m, a *negative* exponent results. A value with a negative exponent is equal to the reciprocal of the same value with a positive exponent. Thus, $a^{-n}=\frac{1}{a^n}$ and $\frac{a^2b^{-3}}{c}=\frac{a^2}{b^3c}$.

In raising to a power a number with an exponent, the two exponents are multiplied. Thus $(a^2)^3=a^{2\times 3}=a^6$, or $(a^n)^m=a^{nm}$. The inverse is true in extracting a root. Thus, $\sqrt[3]{a^2}=a^{\frac{2}{3}}=a^{0.667}$, or $\sqrt[m]{a^n}=a^{\frac{n}{m}}$.

Both members of an equation can be multiplied or divided by equal quantities without disturbing the equality, excluding division by zero or some expression equal to zero. Thus, if $a=b+c$, $2a=2(b+c)$, or if $x=y$, $ax=y(b+c)$ and $\frac{a}{x}=\frac{b+c}{y}$. Sometimes there is more than one answer to an equation. Division by one of the unknowns may eliminate one of the answers.

Both members of an equation can be raised to the same power, and like roots of both members can be taken, without disturbing the equality. Thus, if $a=b+c$, $a^2=(b+c)^2$, or if $x=y$, $a^x=(b+c)^y$. This is *not* the same as $a^x=b^y+c^y$. Similarly, if $a=b+c$, $\sqrt{a}=\sqrt{b+c}$, or if $x=y$, $\sqrt[x]{a}=\sqrt[y]{b+c}$. Again, $\sqrt[y]{b+c}$ is *not* equal to $\sqrt[y]{b}+\sqrt[y]{c}$, as a numerical example will indicate: $\sqrt{100}=\sqrt{64+36}$, but $\sqrt{100}$ does not equal $\sqrt{64}+\sqrt{36}$.

If two quantities to be multiplied or divided are *both* positive or *both* negative, the result is positive. Thus, $(+a)\times(+b)=ab$ and $\frac{-a}{-b}=+\frac{a}{b}$. But if the signs are opposite, the answer is negative. Thus, $(+a)\times(-b)=-ab$, and $\frac{-a}{+b}=-\frac{a}{b}$; also, $(-a)\times(+b)=-ab$, and $\frac{+a}{-b}=-\frac{a}{b}$.

In expressions containing both parentheses and brackets, or both of these and braces, the innermost symbols are removed first. Thus, $-\left\{6z-\frac{[x(x+4)-5y]}{y}\right\}=-\left\{6z-\frac{[x^2+4x-5y]}{y}\right\}=-\left\{6z-\frac{x^2}{y}-\frac{4x}{y}+5\right\}=-6z+\frac{x^2}{y}+\frac{4x}{y}-5$.

123. Fractions.—To add or subtract two or more fractions, convert each to an expression having the same denominator, and then add the numerators. Thus, $\frac{a}{b}+\frac{c}{d}+\frac{e}{f}=\frac{adf}{bdf}+\frac{cbf}{bdf}+\frac{ebd}{bdf}=\frac{adf+cbf+ebd}{bdf}$. That is, both numerator and denominator of each fraction are multiplied by the denominator of the other remaining fractions.

To multiply two or more fractions, multiply the numerators by each other, and also multiply the denominators by each other. Thus, $\frac{a}{b}\times\frac{c}{d}\times\frac{e}{f}=\frac{ace}{bdf}$.

To divide two fractions, invert the divisor and multiply. Thus, $\frac{a}{b}\div\frac{c}{d}=\frac{a}{b}\times\frac{d}{c}=\frac{ad}{bc}$.

If the same factor appears in all terms of a fraction, it can be factored out without changing the value of the fraction. Thus, $\frac{ab+ac+ad}{ae-af}=\frac{b+c+d}{e-f}$. This is the same as factoring a from the numerator and denominator separately. That is, $\frac{ab+ac+ad}{ae-af}=\frac{a(b+c+d)}{a(e-f)}$, but since $\frac{a}{a}=1$, this part can be removed, and the fraction appears as above.

124. Transposition.—It is sometimes desirable to move terms of an expression from one side of the equals sign (=) to the other. This is called **transposition,** and to move one term is to **transpose** it. If the term to be moved is preceded by a plus or a minus sign, this sign is reversed when the term is transposed. Thus, if $a=b+c$, then $a-b=c$, $a-c=b$, $-b=c-a$, $-b-c=-a$, etc. Note that the signs of *all* terms can be reversed without destroying the equality, for if $a=b$, $b=a$. Thus, if *all* terms to the left of the equals sign are exchanged for *all* those to the right, no change in sign need take place, yet if each is moved individually, the signs reverse. For instance, if $a=b+c$, $-b-c=-a$. If each term is multiplied by -1, this becomes $b+c=a$.

A term which is to be multiplied or divided by *all* other terms on its side of the equation can be transposed if it is also moved from the numerator to the denominator, or vice versa. Thus, if $a=\frac{b}{c}$, then $ac=b$, $c=\frac{b}{a}$, $\frac{1}{b}=\frac{1}{ac}$, $\frac{c}{b}=\frac{1}{a}$, etc. $\left(\text{Note that } a=\frac{a}{1}.\right)$ The same result could be obtained by multiplying both sides of an equation by the same quantity. For instance, if both sides of $a=\frac{b}{c}$ are multiplied by c, the equation becomes $ac=\frac{bc}{c}$ and since any number (except zero) divided by itself is unity, $\frac{c}{c}=1$, and the equation becomes $ac=b$, as given above. Note, also, that *both* sides of an equation can be *inverted* without destroying the relationship, for if $a=b$, $\frac{a}{1}=\frac{b}{1}$, and $\frac{1}{b}=\frac{1}{a}$ or $\frac{1}{a}=\frac{1}{b}$. This is accomplished by transposing *all* terms of an equation.

Note that in the case of transposition by changing the plus or minus sign, an entire expression must be changed, and not a part of it. Thus, if $a=bc+d$, $a-bc=d$, but it is not true that $a+b=c+d$. Similarly, a term to be transposed by reversing its multiplication-division relationship must bear that relationship to *all* other terms on its side of the equation. That is, if $a=bc+d$, it is *not* true that $\frac{a}{b}=c+d$, or that $\frac{a}{bc}=d$, but $\frac{a}{bc+d}=1$. If $a=b(cd+e)$, then $\frac{a}{b}=cd+e$.

125. Ratio and proportion.—If the relationship of a to b is the same as that of c *to* d, this fact can be written $a : b :: c : d$, or $\frac{a}{b}=\frac{c}{d}$. Either side of this equation, $\frac{a}{b}$ or $\frac{c}{d}$ is called a **ratio** and the whole equation is called a **proportion.** When a ratio is given a numerical value, it is often expressed as a decimal or as a percentage. Thus, if $\frac{a}{b}=\frac{1}{4}$ (that is, $a=1$, $b=4$), the ratio might be expressed as 0.25 or as 25 percent.

Since a ratio is a fraction, it can be handled as any other fraction.

Geometry

126. Definitions.—**Geometry** is that branch of mathematics dealing with the properties, relations, and measurement of lines, surfaces, solids, and angles. **Plane**

geometry deals with plane figures, and **solid geometry** deals with three-dimensional figures.

A **point,** considered mathematically, is a place having position but no extent. It has no length, breadth, or thickness. A point in motion produces a **line,** which has length, but neither breadth nor thickness. A **straight** or **right line** is the shortest distance between two points in space. A line in motion in any direction except along itself produces a **surface,** which has length and breadth, but not thickness. A **plane surface** or **plane** is a surface without curvature. A straight line connecting any two of its points lies wholly within the plane. A plane surface in motion in any direction except within its plane produces a **solid,** which has length, breadth, and thickness. **Parallel** lines or surfaces are those which are everywhere equidistant. **Perpendicular** lines or surfaces are those which meet at right angles. A perpendicular may be called a **normal,** particularly when it is perpendicular to the tangent to a curved line or surface at the point of tangency. All points equidistant from the ends of a straight line are on the perpendicular bisector of that line. The distance from a point to a line is the length of the perpendicular between them, unless some other distance is indicated.

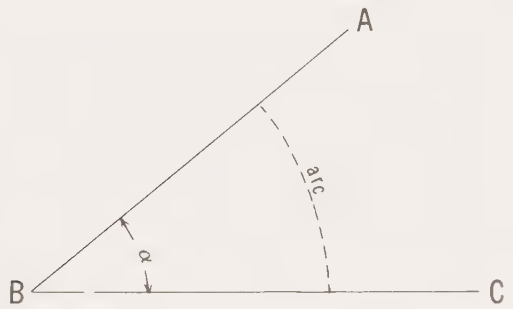

FIGURE 127a.—An angle.

127. Angles.—An **angle** is the inclination to each other of two straight lines which meet at a point. It is measured by the arc of a circle intercepted between the two lines forming the angle, the center of the circle being at the point of intersection. Referring to figure 127a, the angle formed by lines *AB* and *BC*, measured by the arc shown, may be designated "angle *B*," "angle *ABC*," or "angle *CBA*"; or by Greek letter (app. B), as "angle α." The first method should not be used if there is more than one angle at the point, as at *G* in figure 127b. When three letters are used, the middle one should always be that at the **vertex** of the angle, as *G* in figure 127b.

An **acute angle** is one less than a right angle (90°). In figure 127b, angles *AGB*, *BGC*, *CGD*, *DGE*, and *EGF* are all acute angles.

A **right angle** is one whose sides are perpendicular (90°). In figure 127b, angles *AGC*, *BGD*, *CGE*, and *DGF* are right angles.

An **obtuse angle** is one greater than a right angle (90°) but less than a straight angle (180°). In figure 127b, angles *AGD*, *BGE*, and *CGF* are obtuse angles. Angle *AGF* is also obtuse if measured counterclockwise from *AG* to *FG*.

A **straight angle** is one whose sides form a continuous straight line (180°). In figure 127b, angles *AGE* and *BGF* are straight angles.

A **reflex angle** is one greater than a straight angle (180°) but less than a circle (360°). In figure 127b, angle *AGF* is reflex if measured clockwise from *AG* to *FG*. Actually, any two lines meeting at a point form two angles, one less than a straight angle of 180° (unless exactly a straight angle) and the other greater than a straight angle (180°).

An **oblique angle** is any angle not a multiple of 90°.

Two angles whose sum is a right angle (90°) are **complementary angles,** and either is the **complement** of the other. In figure 127b, angles *AGB* and *BGC*, *BGC* and *CGD*, *CGD* and *DGE*, and *DGE* and *EGF* are complementary. The angles need not be adjacent. Angles *AGB* and *DGE*, and angles *BGC* and *EGF* are complementary.

Two angles whose sum is a straight angle (180°) are **supplementary angles,** and either is the **supplement** of the other. In figure 127b, angle AGB and BGE, AGC and CGE, AGD and DGE, BGC and CGF, BGD and DGF, BGE and EGF, and AGC and DGF are supplementary.

Two angles whose sum is a circle (360°) are **explementary angles,** and either is the **explement** of the other. The two angles formed when any two lines terminate at a common point are explementary.

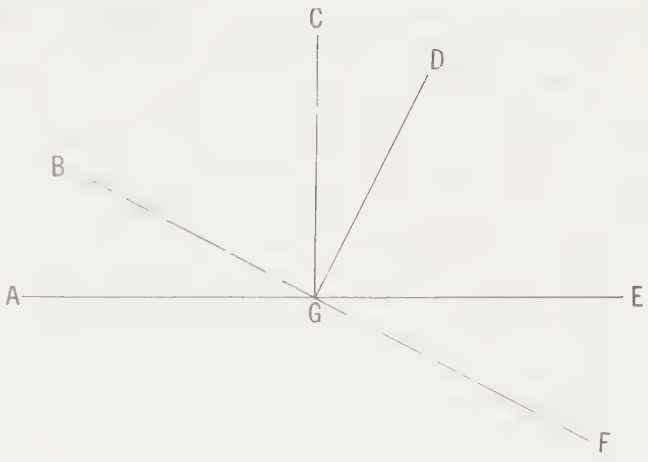

FIGURE 127b.—Acute, right, and obtuse angles.

Since angles AGB and CGD (fig. 127b) are each complementary to angle BGC, angles AGB and CGD are equal. Similarly, it can be shown that angle EGF is also equal to angle CGD (and therefore also equal to angle AGB) and also that angles BGC and DGE are equal to each other. Since AGC and CGE are both right angles with a common side, CG is perpendicular to AE. Similarly, DG is perpendicular to BF. If the sides of one angle are perpendicular to those of another, the two angles are either equal or supplementary. Also, if the sides of one angle are parallel to those of another, the two angles are either equal or supplementary.

When two straight lines intersect, forming four angles, the two opposite angles, called **vertical angles,** are equal. Thus, in figure 127b, lines AE and BF intersect at G. Angles AGB and EGF form a pair of equal acute vertical angles, and BGE and AGF form a pair of equal obtuse vertical angles. Angles which have the same vertex and lie on opposite sides of a common side are **adjacent angles.** Adjacent angles formed by intersecting lines are supplementary, since each pair of adjacent angles forms a straight angle (fig. 127b).

A **transversal** is a line that intersects two or more other lines. If two or more parallel lines are cut by a transversal, groups of adjacent and vertical angles are formed, as shown in figure 127c. In this situation, all acute angles (A) are equal, all obtuse angles (B) are equal, and each acute angle is supplementary to each obtuse angle.

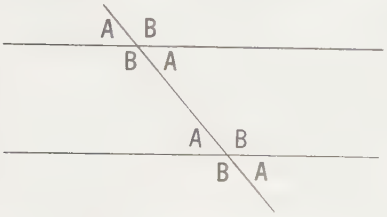

FIGURE 127c.—Angles formed by a transversal.

A **dihedral angle** is the angle between two intersecting planes.

128. Triangles.—A **plane triangle** is a closed figure formed by three straight lines, called **sides,** which meet at three points called **vertices** (singular **vertex**). The vertices are usually labeled with capital letters, and the sides with lowercase letters, as shown in figure 128a.

An **equilateral triangle** is one with its three sides equal. An **equiangular triangle** is one with its three angles equal. When either of these conditions is present, the other always is, so that a triangle which is equilateral is also equiangular, and vice versa.

An **isosceles triangle** is one with two equal sides, called **legs.** The angles opposite the legs are equal. A line which bisects (divides into two equal parts) the *unequal*

angle of an isosceles triangle is the perpendicular bisector of the opposite side, and divides the triangle into two equal right triangles.

A **scalene triangle** is one with no two sides equal. In such a triangle, no two angles are equal.

An **acute triangle** is one with three acute angles.

A **right triangle** is one with a right angle. The side opposite the right angle is called the **hypotenuse.** The other two sides may be called **legs.** A plane triangle can have only one right angle.

An **obtuse triangle** is one with an obtuse angle. A plane triangle can have only one obtuse angle.

An **oblique triangle** is one which does not contain a right angle.

The **altitude** of a triangle is a perpendicular line from any vertex to the opposite side, extended if necessary, or the length of this perpendicular line.

A **median** of a triangle is a line from any vertex to the center of the opposite side. The three medians of a triangle meet at a point called the **centroid** of the triangle. This point divides each median into two parts, that part between the centroid and the vertex being twice as long as the other part.

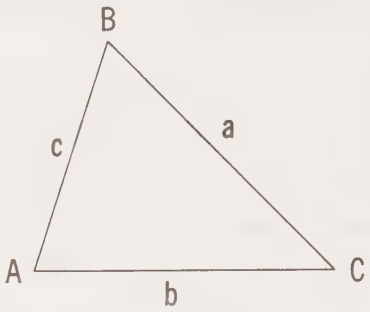

FIGURE 128a.—A triangle.

Lines bisecting the three angles of a triangle meet at a point which is equidistant from the three sides, and is the center of the **inscribed circle,** as shown in figure 128b. This point is of particular interest to navigators because it is the point often taken as the fix when three lines of position of equal weight and having only random errors do not meet at a common point.

The perpendicular bisectors of the three sides of a triangle meet at a point which is equidistant from the three vertices, and is the center of the **circumscribed circle,** the circle through the three vertices and therefore the smallest circle which can be drawn enclosing the triangle. The center of a circumscribed circle is within an acute triangle, on the hypotenuse of a right triangle, and outside an obtuse triangle.

A line connecting the mid points of two sides of a triangle is parallel to the third side and half as long. Also, a line parallel to one side of a triangle and intersecting the other two sides divides these sides proportionally. This principle can be used to divide a line into any number of equal or proportional parts. Refer to figure 128c. Suppose it is desired to divide line AB into four equal parts. From A draw any line AC. Along C measure four equal parts of any convenient lengths (AD, DE, EF, and FG). Draw GB, and through F, E, and D draw lines parallel to GB and intersecting AB. Then AD', $D'E'$, $E'F'$, and $F'B$ are equal and AB is divided into four equal parts.

The sum of the angles of a plane triangle is 180°. Therefore, the sum of the acute angles of a right triangle is 90°, and the angles are complementary. If one side of a triangle is extended, the **exterior angle** thus formed is supplementary to the adjacent **interior angle** and, therefore, equal to the sum of the two nonadjacent angles. If two angles of one triangle are equal to two angles of another triangle, the third angles are also equal, and the triangles are **similar.** If the area of one triangle is equal to the area of another, the triangles are **equal.** Triangles having equal bases and altitudes have equal areas. Two figures are **congruent** if one can be placed over the other to make an exact fit. Congruent figures are both similar and equal. If any side of one triangle is equal to any side of a similar triangle, the triangles are congruent. For example, if two right triangles have equal sides, they are congruent; if two right triangles have

two corresponding sides equal, they are congruent. Triangles are congruent only if the sides and angles are equal.

The sum of two sides of a plane triangle is always greater than the third side; their difference is always less than the third side.

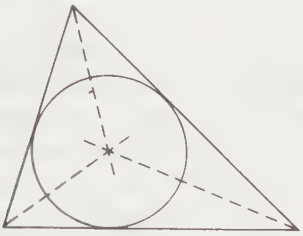

FIGURE 128b.—A circle inscribed in a triangle.

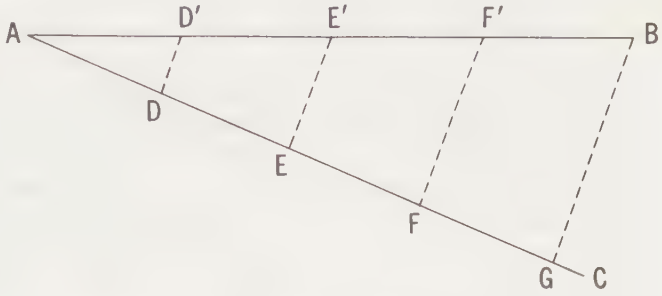

FIGURE 128c.—Dividing a line into equal parts.

If A=area, b=one of the legs of a right triangle or the base of any plane triangle, h=altitude, c=the hypotenuse of a right triangle, a=the other leg of a right triangle, and S=the sum of the interior angles:

Area of plane triangle: $A=\frac{bh}{2}$

Length of hypotenuse of plane right triangle: $c=\sqrt{a^2+b^2}$

Sum of interior angles of plane triangle: $S=180°$.

129. Polygons.—A **polygon** is a closed plane figure made up of three or more straight lines called **sides**. A polygon with three sides is a **triangle,** one with four sides is a **quadrilateral,** one with five sides is a **pentagon,** one with six sides is a **hexagon,** and one with eight sides is an **octagon.** An **equilateral polygon** has equal sides. An **equiangular polygon** has equal interior angles. A **regular polygon** is both equilateral and equiangular. As the number of sides of a regular polygon increases, the figure approaches a circle.

A **trapezoid** is a quadrilateral with one pair of opposite sides parallel and the other pair not parallel. A **parallelogram** is a quadrilateral with both pairs of opposite sides parallel. Any side of a parallelogram, or either of the parallel sides of a trapezoid, is the **base** of the figure. The perpendicular distance from the base to the opposite side is the altitude. A **rectangle** is a parallelogram with four right angles. (If any one is a right angle, the other three must be, also.) A **square** is a rectangle with equal sides. A **rhomboid** is a parallelogram with oblique angles. A **rhombus** is a rhomboid with equal sides.

The sum of the exterior angles of a convex polygon (one having no interior reflex angles), made by extending each side in one direction only (consistently), is 360°.

A **diagonal** of a polygon is a straight line connecting any two vertices which are not adjacent. The diagonals of a parallelogram bisect each other.

The **perimeter** of a polygon is the sum of the lengths of its sides.

If A=area, s=the side of a square, a=that side of a rectangle adjacent to the base or that side of a trapezoid parallel to the base, b=the base of a quadrilateral, h=the altitude of a parallelogram or trapezoid, S=the sum of the angles of a polygon, and n=the number of sides of a polygon:

Area of square: $A=s^2$
Area of rectangle: $A=ab$
Area of parallelogram: $A=bh$
Area of trapezoid: $A=\frac{(a+b)h}{2}$
Sum of angles in convex polygon: $S=(n-2)180°$.

130. Circles.—A **circle** is a plane, closed curve, all points of which are equidistant from a point within, called the **center** (*C*, fig. 130); or the figure formed by such a curve.

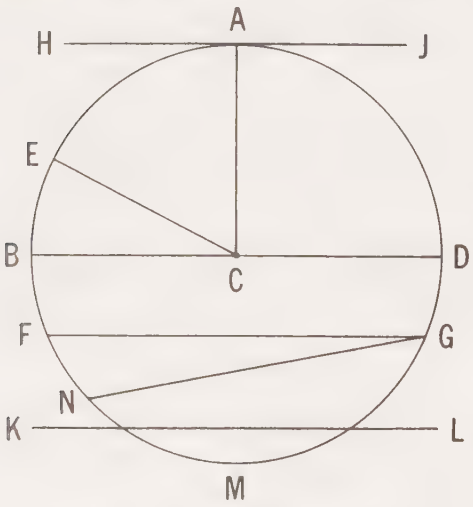

FIGURE 130.—Elements of a circle.

The line forming the circle is called the **circumference.** The length of this line is the **perimeter,** although the term "circumference" is often used with this meaning. An **arc** is part of a circumference. A **major arc** is more than a semicircle (180°), a **minor arc** is less than a semicircle (180°). A **semicircle** is half a circle (180°), a **quadrant** is a quarter of a circle (90°), a **quintant** is a fifth of a circle (72°), a **sextant** is a sixth of a circle (60°), an **octant** is an eighth of a circle (45°). Some of these names have been applied to instruments used by navigators for measuring altitudes of celestial bodies because of the part of a circle originally used for the length of the arc of the instrument.

Concentric circles have a common center.

A **radius** (plural **radii**) or **semidiameter** is a straight line connecting the center of a circle with any point on its circumference. In figure 130, *CA*, *CB*, *CD*, and *CE* are radii.

A **diameter** of a circle is a straight line passing through its center and terminating at opposite sides of the circumference, or two radii in opposite directions (*BCD*, fig. 130). It divides a circle into two equal parts. The ratio of the length of the circumference of any circle to the length of its diameter is 3.14159+, or π (the Greek letter *pi*), a relationship that has many useful applications.

A **sector** is that part of a circle bounded by two radii and an arc. In figure 130, *BCE*, *ECA*, *ACD*, *BCA*, and *ECD* are sectors. The angle formed by two radii is called a **central angle**. Any pair of radii divides a circle into sectors, one less than a semicircle (180°) and the other greater than a semicircle (unless the two radii form a diameter).

A **chord** is a straight line connecting any two points on the circumference of a circle (*FG*, *GN* in fig. 130). Chords equidistant from the center of a circle are equal in length.

A **segment** is that part of a circle bounded by a chord and the intercepted arc (*FGMF*, *NGMN* in fig. 130). A chord divides a circle into two segments, one less than a semicircle (180°), and the other greater than a semicircle (unless the chord is a diameter). A diameter perpendicular to a chord bisects it, its arc, and its segments. Either pair of vertical angles formed by intersecting chords has a combined number of degrees equal to the sum of the number of degrees in the two arcs intercepted by the two angles.

An **inscribed angle** is one whose vertex is on the circumference of a circle and whose sides are chords (*FGN* in fig. 130). It has half as many degrees as the arc it intercepts. Hence, an angle inscribed in a semicircle is a right angle if its sides terminate at the ends of the diameter forming the semicircle.

A **secant** of a circle is a line intersecting the circle, or a chord extended beyond the circumference (*KL* in fig. 130).

A **tangent** to a circle is a straight line, in the plane of the circle, which has only one point in common with the circumference (*HJ* in fig. 130). A tangent is perpendicular to the radius at the **point of tangency** (*A* in fig. 130). The two tangents from a point to opposite sides of a circle are equal in length, and a line from the point to the center of the circle bisects the angle formed by the two tangents. An angle formed outside a circle by the intersection of two tangents, a tangent and a secant, or two secants has *half* as many degrees as the *difference* between the two intercepted arcs. An angle formed by a tangent and a chord, with the apex at the point of tangency, has half as many degrees as the arc it intercepts. A **common tangent** is one tangent to more than one circle. Two circles are tangent to each other if they touch at one point only. If of different sizes, the smaller circle may be either inside or outside the larger one.

Parallel lines intersecting a circle intercept equal arcs.

If A=area; r=radius; d=diameter; C=circumference; s=linear length of an arc; α=angular length of an arc, or the angle it subtends at the center of a circle, in degrees; β=angular length of an arc, or the angle it subtends at the center of a circle, in radians; rad=radians (art. 138), and sin=sine (art. 139):

Area of circle: $A=\pi r^2=\frac{\pi d^2}{4}$

Circumference of circle: $C=2\pi r=\pi d=2\pi$ rad

Area of sector: $A=\frac{\pi r^2 \alpha}{360}=\frac{r^2\beta}{2}=\frac{rs}{2}$

Area of segment: $A=\frac{r^2(\beta-\sin\alpha)}{2}$.

131. Polyhedrons.—A **polyhedron** is a solid having plane sides or **faces.**

A **cube** is a polyhedron having six square sides.

A **prism** is a solid having parallel, similar, equal, plane geometric figures as bases, and parallelograms as sides. By extension, the term is also applied to a similar solid having nonparallel bases, and trapezoids or a combination of trapezoids and parallelograms as sides. The **axis** of a prism is the straight line connecting the centers of its bases. A **right prism** is one having bases perpendicular to the axis. The sides of a right prism are rectangles. A **regular prism** is a right prism having regular polygons as bases. The **altitude** of a prism is the perpendicular distance between the planes of its bases. In the case of a right prism, it is measured along the axis.

A **pyramid** is a polyhedron having a polygon as one end, the **base;** and a point, the **apex,** as the other; the two ends being connected by a number of triangular sides or **faces.** The **axis** of a pyramid is the straight line connecting the apex and the center of the base. A **right pyramid** is one having its base perpendicular to its axis. A **regular pyramid** is a right pyramid having a regular polygon as its base. The **altitude** of a pyramid is the perpendicular distance from its apex to the plane of its base. A **truncated pyramid** is that portion of a pyramid between its base and a plane intersecting all of the faces of the pyramid.

If A=area, s=edge of a cube or slant height of a regular pyramid (from the center of one side of its base to the apex), V=volume, a=side of a polygon, h=altitude, P=perimeter of base, n=number of sides of polygon, B=area of base, and r=perpendicular distance from the center of a side of a polygon to the center of the polygon:

Cube:

Area of each face: $A=s^2$
Total area of all faces: $A=6s^2$
Volume: $V=s^3$.

Regular prism:

Area of each face: $A=ah$
Total area of all faces: $A=Ph=nah$

Area of each base: $B=\frac{nar}{2}$

Total area of both bases: $A=nar$

Volume: $V=Bh=\frac{narh}{2}$.

Regular pyramid:

Area of each face: $A=\frac{as}{2}$

Total area of all faces: $A=\frac{nas}{2}$

Area of base: $B=\frac{nar}{2}$

Volume: $V=\frac{Bh}{3}=\frac{narh}{6}$.

132. Cylinders.—A **cylinder** is a solid having two parallel plane **bases** bounded by closed congruent curves, and a surface formed by an infinite number of parallel lines, called **elements,** connecting similar points on the two curves. A cylinder is similar to a prism, but with a curved lateral surface, instead of a number of flat sides connecting the bases. The **axis** of a cylinder is the straight line connecting the centers of the bases. A **right cylinder** is one having bases perpendicular to the axis. A **circular cylinder** is one having circular bases. The **altitude** of a cylinder is the perpendicular distance between the planes of its bases. The **perimeter** of a base is the length of the curve bounding it.

If A=area, P=perimeter of base, h=altitude, r=radius of a circular base, B=area of base, and V=volume, then for a right circular cylinder:

Lateral area: $A=Ph=2\pi rh$
Area of each base: $B=\pi r^2$
Total area, both bases: $A=2\pi r^2$
Volume: $V=Bh=\pi r^2h$.

133. Cones.—A **cone** is a solid having a plane **base** bounded by a closed curve, and a surface formed by lines, called **elements,** from every point on the curve to a common point called the **apex.** A cone is similar to a pyramid, but with a curved

surface connecting the base and apex, instead of a number of flat sides. The **axis** of a cone is the straight line connecting the apex and the center of the base. A **right cone** is one having its base perpendicular to its axis. A **circular cone** is one having a circular base. The **altitude** of a cone is the perpendicular distance from its apex to the plane of its base. A **frustum** of a cone is that portion of the cone between its base and any parallel plane intersecting all elements of the cone. A **truncated cone** is that portion of a cone between its base and any nonparallel plane which intersects all elements of the cone but does not intersect the base.

If A=area, r=radius of base, s=slant height or length of element, B=area of base, h=altitude, and V=volume, then for a right circular cone:

Lateral area: $A=\pi rs$
Area of base: $B=\pi r^2$
Slant height: $s=\sqrt{r^2+h^2}$
Volume: $V=\frac{Bh}{3}=\frac{\pi r^2 h}{3}$.

FIGURE 134a.—Conic sections.

134. Conic sections.—If a right circular cone of indefinite extent is intersected by a plane perpendicular to the axis of the cone (AB, fig. 134a), the line of intersection of the plane and the surface of the cone is a **circle.**

If the intersecting plane of figure 134a is tilted to some position such as CD, the intersection is an **ellipse** or flattened circle, figure 134b. The longest diameter of an ellipse is called its **major axis,** and half of this is its **semimajor axis, *a*.** The shortest diameter of an ellipse is called its **minor axis,** and half of this is its **semiminor axis, *b*.** Two points, F and F', called **foci** (singular **focus**) or **focal points,** on the major axis are so located that the sum of their distances from any point P on the curve is equal to the length of the major axis. That is, $PF+PF'=2a$ (fig. 134b). The **eccentricity** (*e*) of an ellipse is equal to $\frac{c}{a}$, where c is the distance from the center to one of the foci ($c=CF=CF'$). It is always greater than 0 but less than 1.

If the intersecting plane of figure 134a is parallel to one element of the cone, as at EF, the intersection is a **parabola,** figure 134c. Any point P on a parabola is equi-

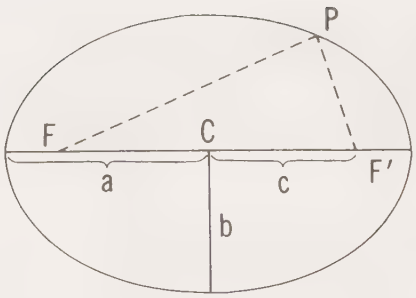

FIGURE 134b.—An ellipse.

distant from a fixed point F, called the **focus** or **focal point,** and a fixed straight line, AB, called the **directrix.** Thus, for any point P, $PF=PE$. The point midway between the focus F and the directrix AB is called the **vertex,** V. The straight line through F and V is called the **axis,** CD. This line is perpendicular to the directrix AB. The **eccentricity** (e) of a parabola is 1.

If the elements of the cone of figure 134a are extended to form a second cone having the same axis and apex but extending in the opposite direction, and the intersecting plane is tilted beyond the position forming a parabola, so that it intersects both curves, as at GH, the intersections of the plane with the cones is a **hyperbola,** figure 134d. There are two intersections or branches of a hyperbola, as shown. At any point P on either branch, the *difference* in the distance from two fixed points called **foci** or **focal points,** F and F', is constant and equal to the shortest distance between the two branches. That

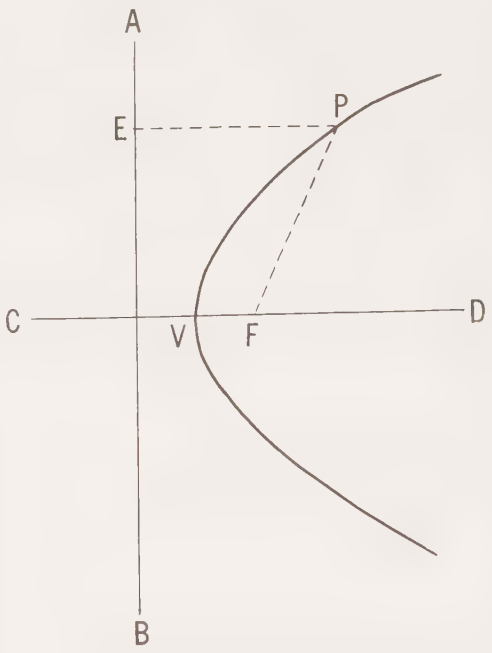

FIGURE 134c.—A parabola.

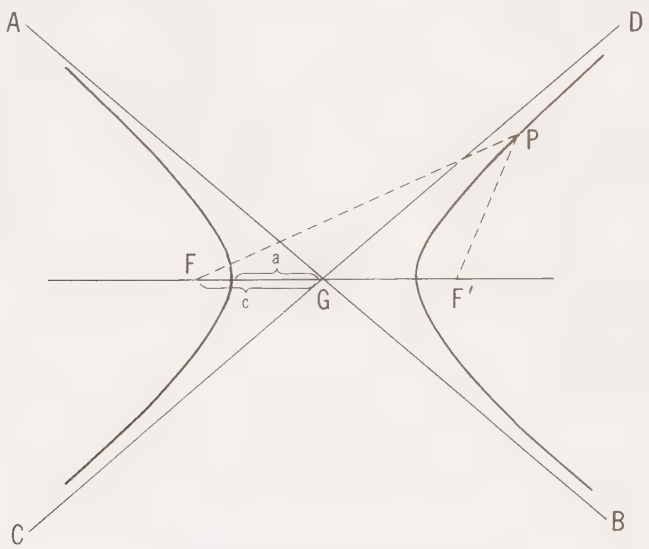

FIGURE 134d.—A hyperbola.

is, $PF-PF'=2a$ (fig. 134d). The straight line through F and F' is called the **axis.** The **eccentricity** (e) of a hyperbola is the ratio $\frac{c}{a}$ (fig. 134d). It is always greater than 1.

Each branch of a hyperbola approaches ever closer to, but never reaches, a pair of intersecting straight lines, AB and CD, called **asymptotes.** These intersect at G.

The various conic sections bear an eccentricity relationship to each other. The eccentricity of a circle is 0, that of an ellipse is greater than 0 but less than 1, that of a parabola or straight line (a limiting case of a parabola) is 1, and that of a hyperbola is greater than 1.

If e=eccentricity, A=area, a=semimajor axis of an ellipse or half the shortest distance between the two branches of a hyperbola, b=the semiminor axis of an ellipse, and c=the distance between the center of an ellipse and one of its focal points or the distance between the focal point of a hyperbola and the intersection of its asymptotes:

Circle:

Eccentricity: $e=0$

Other relationships given in article 130.

Ellipse:

Area: $A=\pi ab$

Eccentricity: $e=\frac{c}{a}$, greater than 0, but less than 1.

Parabola:

Eccentricity: $e=1$.

Hyperbola:

Eccentricity: $e=\frac{c}{a}$, greater than 1.

When cones are intersected by some surface other than a plane, as the curved surface of the earth, the resulting sections do not follow the relationships given above, the amount of divergence therefrom depending upon the individual circumstances.

135. Spheres.—A sphere is a solid bounded by a surface every point of which is equidistant from a point within, called the **center.** It may be formed by rotating a circle about any diameter.

A **radius** or **semidiameter** of a sphere is a straight line connecting its center with any point on its surface. A **diameter** of a sphere is a straight line through its center and terminated at both ends by the surface of the sphere. The poles of a sphere are the ends of a diameter.

The intersection of a plane and the surface of a sphere is a circle, a **great circle** if the plane passes through the center of the sphere, and a **small circle** if it does not. The shorter arc of the great circle between two points on the surface of a sphere is the shortest distance, on the surface of the sphere, between the points. Every great circle of a sphere bisects every other great circle of that sphere. The **poles** of a circle on a sphere are the extremities of the sphere's diameter which is perpendicular to the plane of the circle. All points on the circumference of the circle are equidistant from either of its poles. In the case of a great circle, *both* poles are 90° from any point on the circumference of the circle. Any great circle may be considered a **primary,** particularly when it serves as the origin of measurement of a coordinate. The great circles through its poles are called **secondaries.** Secondaries are perpendicular to their primary.

A **spherical triangle** is the figure formed on the surface of a sphere by the intersection of three great circles. The lengths of the sides of a spherical triangle are measured in degrees, minutes, and seconds, as the angular lengths of the arcs forming them. The sum of the three sides is always less than 360°. The sum of the three angles is always *more* than 180° and *less* than 540°.

A **lune** is that part of the surface of a sphere bounded by halves of two great circles.

A **spheroid** is a flattened sphere, which may be formed by rotating an ellipse about one of its axes. An **oblate spheroid,** such as the earth, is formed when an ellipse is rotated about its minor axis. In this case the diameter along the axis of rotation is less than the major axis. A **prolate spheroid** is formed when an ellipse is rotated about its major axis. In this case the diameter along the axis of rotation is greater than the minor axis.

If A=area, r=radius, d=diameter, and V=volume of a sphere:

$$\text{Area: } A=4\pi r^2=\pi d^2$$

$$\text{Volume: } V=\frac{4\pi r^3}{3}=\frac{\pi d^3}{6}.$$

If A=area, a=semimajor axis, b=semiminor axis, e=eccentricity, and V=volume of an oblate spheroid:

$$\text{Area: } A=4\pi a^2\left(1-\frac{e^2}{3}-\frac{e^4}{15}-\frac{e^6}{35}-\cdots\right)$$

$$\text{Eccentricity: } e=\sqrt{\frac{a^2-b^2}{a^2}}$$

$$\text{Volume: } V=\frac{4\pi a^2 b}{3}.$$

136. Coordinates are magnitudes used to define a position. Many different types of coordinates are used.

If a position is known to be at a stated point, no magnitudes are needed to identify the position, although they may be required to locate the point. Thus, if a vessel is at port A, its position is known if the location of port A is known, but latitude and longitude may be needed to locate port A.

If a position is known to be on a given line, a single magnitude (coordinate) is needed to identify the position if an origin is stated or understood. Thus, if a vessel is known to be *south* of port B, it is known to be on a line extending southward from port B. If its distance from port B is known, and the position of port B is known, the position of the vessel is uniquely defined.

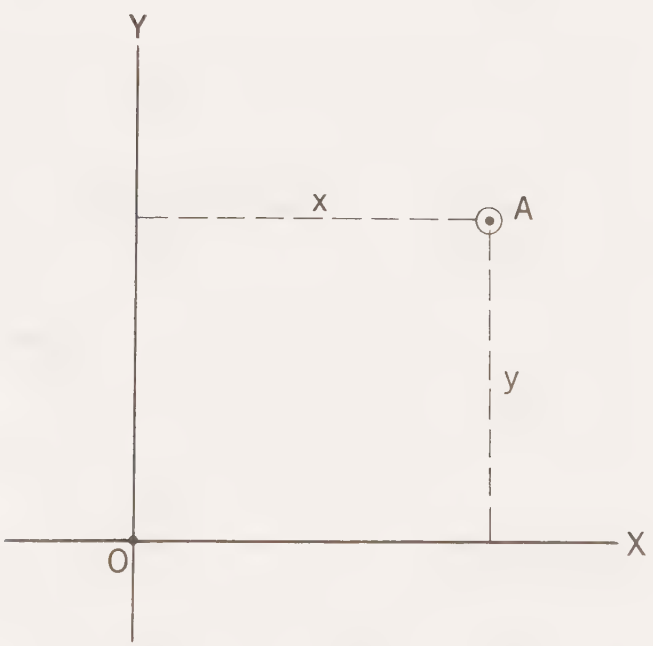

FIGURE 136a.—Rectangular coordinates.

If a position is known to be on a given surface, two magnitudes (coordinates) are needed to define the position. Thus, if a vessel is known to be on the surface of the earth, its position can be identified by means of latitude and longitude. Latitude indicates its angular distance north or south of the equator, and longitude its angular distance east or west of the prime meridian.

If nothing is known regarding a position other than that it exists in space, three magnitudes (coordinates) are needed to define its position. Thus, the position of a submarine may be defined by means of latitude, longitude, and depth below the surface.

Each coordinate requires an origin, either stated or implied. If a position is known to be on a given plane, it might be defined by means of its distance from each of two intersecting lines, called **axes.** Thus, in figure 136a the position of point A can be defined by stating that it is x units to the right of line OY and y units upward from line OX. These are called **rectangular coordinates.** The coordinate along OY is called the **ordinate,** and the coordinate along OX is called the **abscissa.** Point O is the **origin,** and lines OX and OY the **axes** (called the X and Y axes, respectively). Point A is at position x, y. If the axes are not perpendicular but the lines x and y are drawn parallel to the axes, **oblique coordinates** result. Either type are **Cartesian coordinates.** A three-dimensional system of Cartesian coordinates, with X, Y, and Z axes, is called **space coordinates.**

Another system of plane coordinates in common usage consists of the *direction* and *distance* from the origin (called the **pole**), as shown in figure 136b. A line extending in the direction indicated is called a **radius vector.** Direction and distance from a fixed point constitute **polar coordinates,** sometimes called the rho- (the Greek ρ, to indicate distance) theta (the Greek θ, to indicate direction) system. An example of its use is with respect to a radar PPI.

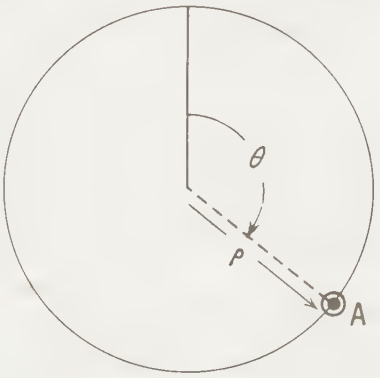

FIGURE 136b.—Polar coordinates.

Spherical coordinates are used to define a position on the surface of a sphere or spheroid by indicating angular distance from a primary great circle and a reference secondary great circle Familiar examples are latitude and longitude, altitude and azimuth, and declination and hour angle.

Trigonometry

137. Definitions.—Trigonometry is that branch of mathematics dealing with the relations among the angles and sides of triangles. **Plane trigonometry** is that branch dealing with plane triangles, and **spherical trigonometry** is that branch dealing with spherical triangles.

138. Angular measure.—A circle may be divided into 360 **degrees** (°), which is the **angular length** of its circumference. Each degree may be divided into 60 **minutes** (′), and each minute into 60 **seconds** (″). The angular length of an arc is usually expressed in these units. By this system a right angle or quadrant has 90° and a straight angle or semicircle 180°. In marine navigation, altitudes, latitudes, and longitudes are usually expressed in degrees, minutes, and tenths (27°14′.4). Azimuths are usually expressed in degrees and tenths (164°.7). The system of degrees, minutes, and seconds indicated above is the **sexagesimal system.** In the **centesimal system,** used chiefly in France, the circle is divided into 400 **centesimal degrees** (sometimes called **grades**) each of which is divided into 100 **centesimal minutes** of 100 **centesimal seconds** each.

A **radian** is the angle subtended at the center of a circle by an arc having a linear length equal to the radius of the circle. A radian is equal to 57°.2957795131 approximately, or 57°17′44″.80625 approximately. The radian is sometimes used as a unit of angular measure. A circle $(360°)=2\pi$ radians, a semicircle $(180°)=\pi$ radians, a right angle $(90°)=\frac{\pi}{2}$ radians, and $1'=0.0002908882$ radians approximately. The length of the arc of a circle is equal to the radius multiplied by the angle subtended in radians.

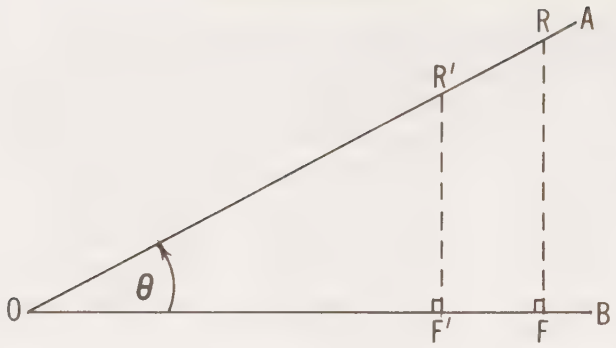

FIGURE 139a.—Similar right triangles.

139. Trigonometric functions are the various proportions or ratios of the sides of a plane right triangle, defined in relation to one of the acute angles. In figure 139a, let θ be any acute angle. From any point R on line OA draw a line perpendicular to OB at F. From any other point R′ on OA, draw a line perpendicular to OB at F′. Then triangles OFR and OF′R′ are similar right triangles because all their corresponding angles are equal. Since in any pair of similar triangles the ratio of any two sides of one triangle is equal to the ratio of the corresponding two sides of the other triangle,

$$\frac{RF}{OF}=\frac{R'F'}{OF'}, \frac{RF}{OR}=\frac{R'F'}{OR'}, \text{ and } \frac{OF}{OR}=\frac{OF'}{OR'}.$$

Irrespective of where the point R is located on OA, the ratio between the lengths of any two sides in the triangle OFR has a constant value. Hence, for any value of the acute angle θ, there is a fixed set of values for the ratios of the various sides of the triangle. These ratios are defined as follows:

$$\text{sine } \theta=\sin\theta=\frac{\text{side opposite}}{\text{hypotenuse}} \qquad \text{cosecant } \theta=\csc\theta=\frac{\text{hypotenuse}}{\text{side opposite}}$$

$$\text{cosine } \theta=\cos\theta=\frac{\text{side adjacent}}{\text{hypotenuse}} \qquad \text{secant } \theta=\sec\theta=\frac{\text{hypotenuse}}{\text{side adjacent}}$$

$$\text{tangent } \theta=\tan\theta=\frac{\text{side opposite}}{\text{side adjacent}} \qquad \text{cotangent } \theta=\cot\theta=\frac{\text{side adjacent}}{\text{side opposite}}.$$

Of these six principal functions, the second three are the reciprocals of the first three. Thus,

$$\sin\theta=\frac{1}{\csc\theta} \qquad \csc\theta=\frac{1}{\sin\theta}$$

$$\cos\theta=\frac{1}{\sec\theta} \qquad \sec\theta=\frac{1}{\cos\theta}$$

$$\tan\theta=\frac{1}{\cot\theta} \qquad \cot\theta=\frac{1}{\tan\theta}.$$

In figure 139b, A, B, and C are the angles of a plane right triangle, the right angle being at C. The sides are a, b, c, as shown. The six principal trigonometric functions of angle B are:

$$\sin B=\frac{b}{c}=\cos A=\cos(90°-B) \qquad \cot B=\frac{a}{b}=\tan A=\tan(90°-B)$$

$$\cos B=\frac{a}{c}=\sin A=\sin(90°-B) \qquad \sec B=\frac{c}{a}=\csc A=\csc(90°-B)$$

$$\tan B=\frac{b}{a}=\cot A=\cot(90°-B) \qquad \csc B=\frac{c}{b}=\sec A=\sec(90°-B).$$

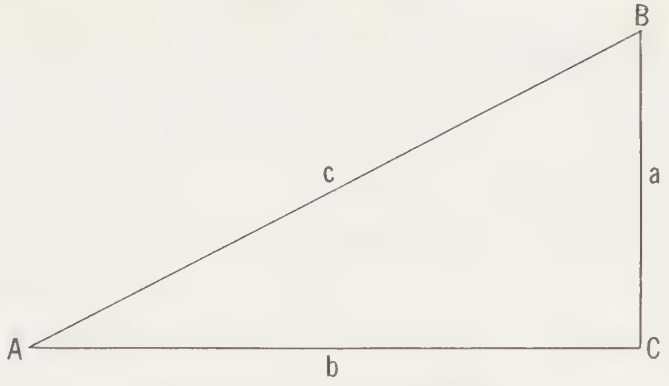

FIGURE 139b.—A right triangle.

Since A and B are *complementary*, these relations show that the sine of an angle is the cosine of its complement, the tangent of an angle is the cotangent of its complement, and the secant of an angle is the cosecant of its complement. Thus, the **co** function of an angle is the function of its complement.

$$\sin (90°-A) = \cos A \qquad \csc (90°-A) = \sec A$$
$$\cos (90°-A) = \sin A \qquad \sec (90°-A) = \csc A$$
$$\tan (90°-A) = \cot A \qquad \cot (90°-A) = \tan A.$$

Certain additional relations are also classed as trigonometric functions:

versed sine θ=versine θ=vers θ=ver θ=1−cos θ
versed cosine θ=coversed sine θ=coversine θ=covers θ=cov θ=1−sin θ
haversine θ=hav θ=½ ver θ=½ (1−cos θ).

The numerical value of a trigonometric function is sometimes called the **natural function** to distinguish it from the logarithm of the function, called the **logarithmic function.** Numerical values of the six principal functions are given at 1′ intervals in table 31. Logarithms are given at the same intervals in table 33. Both natural and logarithmic haversines are given in table 34.

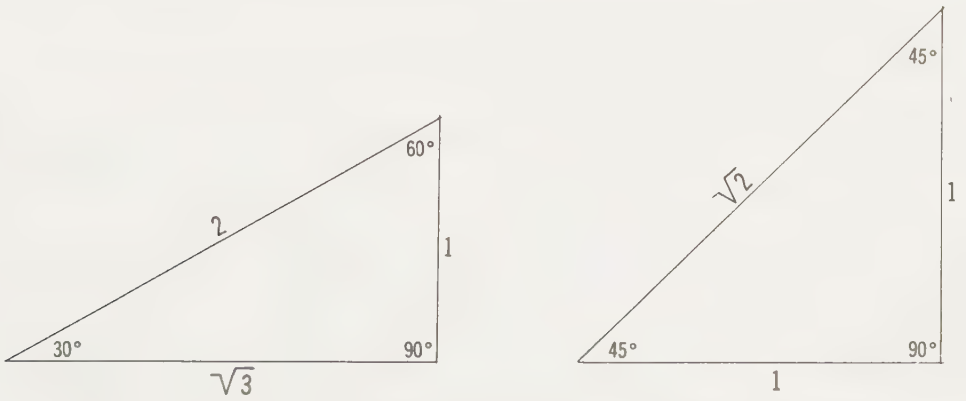

FIGURE 139c.—Numerical relationship of sides of 30°–60° and 45° triangles.

Since the relationships of 30°–60° and 45° right triangles are as shown in figure 139c, certain values of the basic functions can be stated exactly as shown in the following table:

Function	*30°*	*45°*	*60°*
sine	$\frac{1}{2}$	$\frac{1}{\sqrt{2}}=\frac{1}{2}\sqrt{2}$	$\frac{\sqrt{3}}{2}=\frac{1}{2}\sqrt{3}$
cosine	$\frac{\sqrt{3}}{2}=\frac{1}{2}\sqrt{3}$	$\frac{1}{\sqrt{2}}=\frac{1}{2}\sqrt{2}$	$\frac{1}{2}$
tangent	$\frac{1}{\sqrt{3}}=\frac{1}{3}\sqrt{3}$	$\frac{1}{1}=1$	$\frac{\sqrt{3}}{1}=\sqrt{3}$
cotangent	$\frac{\sqrt{3}}{1}=\sqrt{3}$	$\frac{1}{1}=1$	$\frac{1}{\sqrt{3}}=\frac{1}{3}\sqrt{3}$
secant	$\frac{2}{\sqrt{3}}=\frac{2}{3}\sqrt{3}$	$\frac{\sqrt{2}}{1}=\sqrt{2}$	$\frac{2}{1}=2$
cosecant	$\frac{2}{1}=2$	$\frac{\sqrt{2}}{1}=\sqrt{2}$	$\frac{2}{\sqrt{3}}=\frac{2}{3}\sqrt{3}$

TABLE 139a.—Values of various trigonometric functions for angles of 30°, 45°, and 60°.

All trigonometric functions can be shown as lengths of lines in a unit circle. In figure 139d,

sin θ=RF	cot θ=AB
cos θ=OF	sec θ=OD
tan θ=DE	csc θ=OA
ver θ=FE	cov θ=BC.

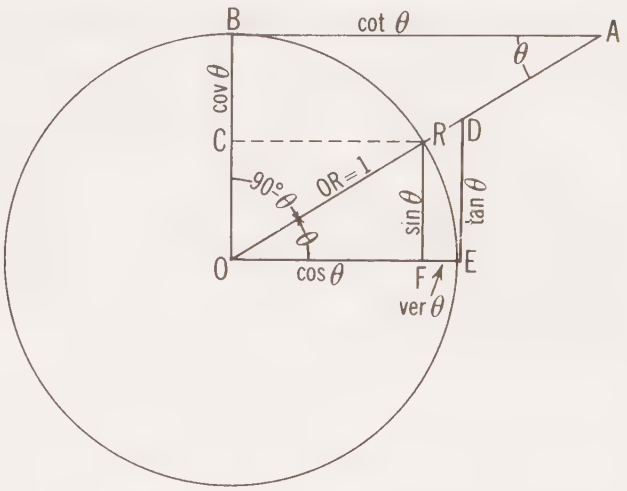

FIGURE 139d.—Line definitions of trigonometric functions.

140. The functions in various quadrants.—To make the definitions of the trigonometric functions more general to include those angles greater than 90°, the functions are defined in terms of the rectangular cartesian coordinates of point R of figure 139a, due regard being given to the sign of the function. In figure 140a, OR is assumed to be a unit radius. By convention the sign of OR is always positive. This radius is imagined to rotate in a counterclockwise direction through 360° from the horizontal position at 0°, the positive direction along the X-axis. Ninety degrees (90°) is the positive direction along the Y-axis. The angle between the original position of the radius and its position at any time increases from 0° to 90° in the *first quadrant* (I), 90° to 180° in the *second quadrant* (II), 180° to 270° in the *third quadrant* (III), and 270° to 360° in the *fourth quadrant* (IV).

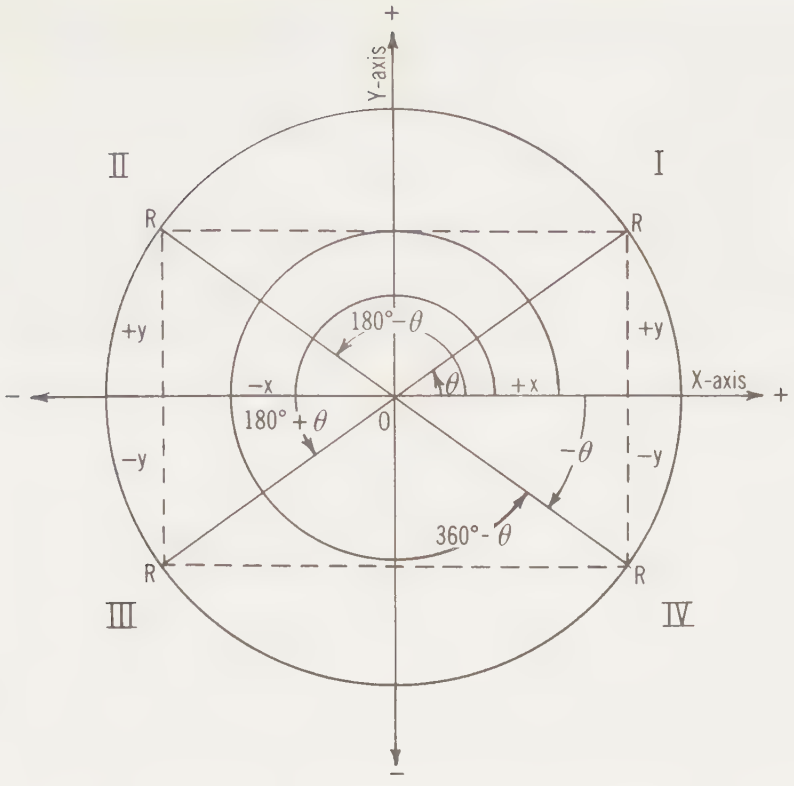

FIGURE 140a.—The functions in various quadrants.

The numerical value of the sine of an angle is equal to the projection of the unit radius on the Y-axis. According to the definition given in article 139, the sine of angle θ in the first quadrant of figure 140a is $\frac{+y}{+OR}$. Radius OR being equal to one, $\sin \theta = +y$. Since $+y$ is equal to the projection of the unit radius OR on the Y-axis, the sine function of an angle in the first quadrant defined in terms of rectangular cartesian coordinates does not contradict the definition in article 139. In figure 140a,

$$\sin \theta = +y$$
$$\sin (180° - \theta) = +y = \sin \theta$$
$$\sin (180° + \theta) = -y = -\sin \theta$$
$$\sin (360° - \theta) = -y = \sin (-\theta) = -\sin \theta.$$

The numerical value of the cosine of an angle is equal to the projection of the unit radius on the X-axis. In figure 140a,

$$\cos \theta = +X$$
$$\cos (180° - \theta) = -X = -\cos \theta$$
$$\cos (180° + \theta) = -X = -\cos \theta$$
$$\cos (360° - \theta) = +X = \cos (-\theta) = \cos \theta.$$

The numerical value of the tangent of an angle is equal to the ratio of the projections of the unit radius on the Y- and X-axes. In figure 140a,

$$\tan \theta = \frac{+y}{+x} \qquad \tan (180° + \theta) = \frac{-y}{-x} = \tan \theta$$

$$\tan (180° - \theta) = \frac{+y}{-x} = -\tan \theta \qquad \tan (360° - \theta) = \frac{-y}{+x} = \tan (-\theta) = -\tan \theta.$$

The cosecant, secant, and cotangent functions of angles in the various quadrants are similarly determined:

$$\csc\theta=\frac{1}{+y} \qquad \sec(180°+\theta)=\frac{1}{-x}=-\sec\theta$$

$$\csc(180°-\theta)=\frac{1}{+y}=\csc\theta \qquad \sec(360°-\theta)=\frac{1}{+x}=\sec(-\theta)=\sec\theta$$

$$\csc(180°+\theta)=\frac{1}{-y}=-\csc\theta \qquad \cot\theta=\frac{+x}{+y}$$

$$\csc(360°-\theta)=\frac{1}{-y}=\csc(-\theta)=-\csc\theta \qquad \cot(180°-\theta)=\frac{-x}{+y}=-\cot\theta$$

$$\sec\theta=\frac{1}{+x} \qquad \cot(180°+\theta)=\frac{-x}{-y}=\cot\theta$$

$$\sec(180°-\theta)=\frac{1}{-x}=-\sec\theta \qquad \cot(360°-\theta)=\frac{+x}{-y}=\cot(-\theta)=-\cot\theta.$$

The signs of the functions are shown in the following table:

Functions	I	II	III	IV
sine and cosecant	+	+	−	−
cosine and secant	+	−	−	+
tangent and cotangent	+	−	+	−
versine, coversine, and haversine	+	+	+	+

TABLE 140a.—Signs of trigonometric functions by quadrant.

The numerical values vary as shown in the following table and in figure 140b.

Functions	I	II	III	IV

TABLE 140b.—Values of trigonometric functions in various quadrants. These relationships are shown graphically in figure 140b.

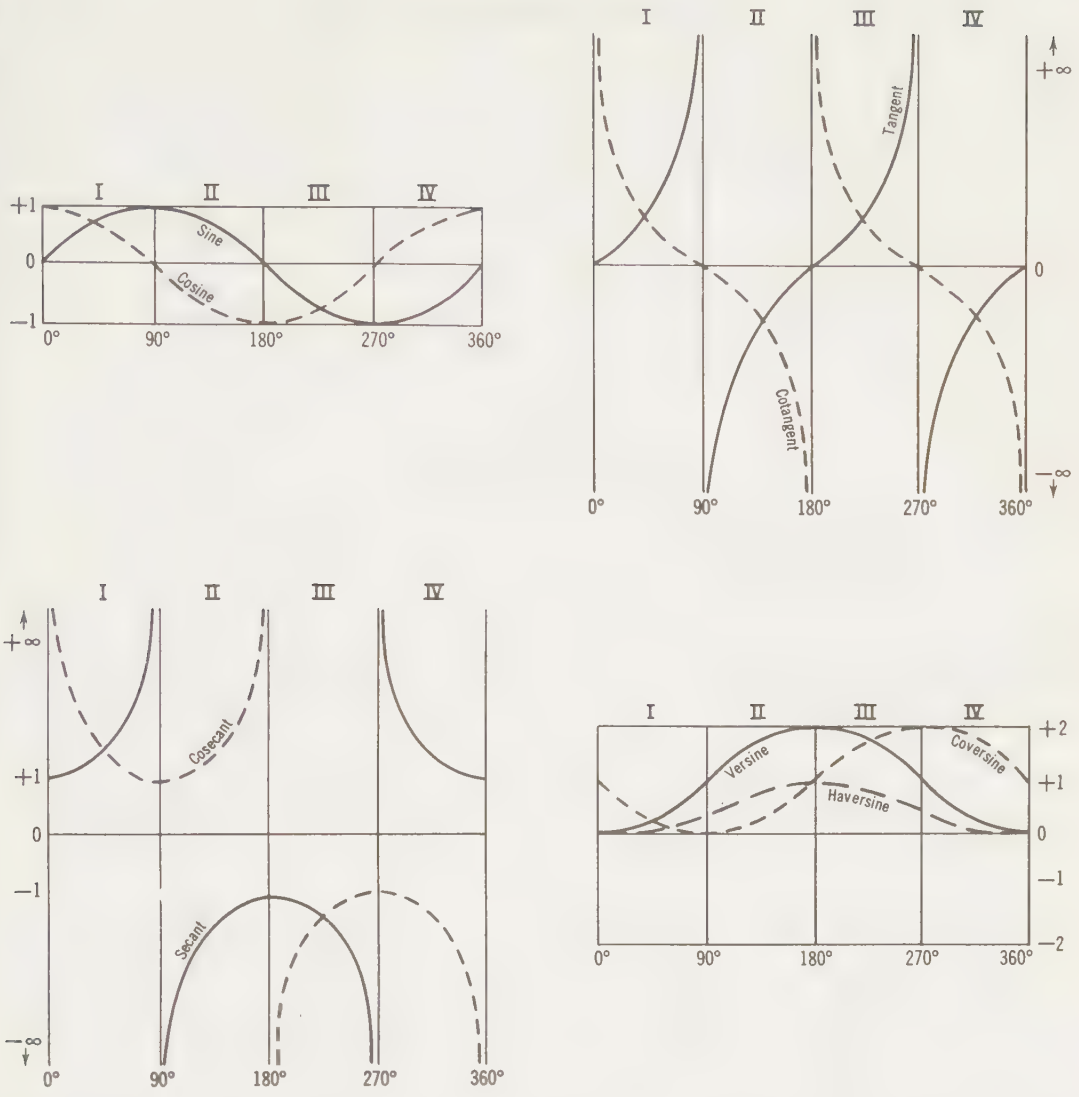

FIGURE 140b.—Graphic representation of values of trigonometric functions in various quadrants.

A **negative angle** $(-\theta)$ is an angle measured in a clockwise direction or in a direction opposite to that of a positive angle. The functions of a negative angle and the corresponding functions of a positive angle are as follows:

$$\sin\ (-\theta) = -\sin\ \theta$$
$$\cos\ (-\theta) = \cos\ \theta$$
$$\tan\ (-\theta) = -\tan\ \theta$$
$$\tan\ (-\theta) = \tan\ (360° - \theta).$$

A **trigonometric identity** is an equality involving trigonometric functions of θ which is true for all values of θ, except those values for which one of the functions is not defined or for which a denominator in the equality is equal to zero. The **fundamental identities** are those identities from which other identities can be derived.

Fundamental Trigonometric Identities

$$\sin\theta=\frac{1}{\csc\theta} \qquad \csc\theta=\frac{1}{\sin\theta}$$

$$\cos\theta=\frac{1}{\sec\theta} \qquad \sec\theta=\frac{1}{\cos\theta}$$

$$\tan\theta=\frac{1}{\cot\theta} \qquad \cot\theta=\frac{1}{\tan\theta}$$

$$\tan\theta=\frac{\sin\theta}{\cos\theta} \qquad \cot\theta=\frac{\cos\theta}{\sin\theta}$$

$$\sin^2\theta+\cos^2\theta=1 \qquad \tan^2\theta+1=\sec^2\theta$$

$$1+\cot^2\theta=\csc^2\theta$$

141. Inverse trigonometric functions.—The angle having a given trigonometric function may be indicated in any of several ways. Thus, $\sin y=x$, $y=\text{arc sin } x$, and $y=\sin^{-1}x$ have the same meaning. The superior -1 is not an exponent in this case. In each case, y is "the angle whose sine is x." In this case, y is the **inverse sine** of x. Similar relationships hold for all trigonometric functions.

142. Solution of triangles.—A triangle is composed of six parts: three angles and three sides. The angles may be designated A, B, and C; and the sides opposite these angles as a, b, and c, respectively. In general, when three parts are known, the other three parts can be found, unless the known parts are the three angles of a plane triangle.

Right plane triangles.—In a right plane triangle it is only necessary to substitute numerical values in the appropriate formulas representing the basic trigonometric functions (art. 139) and solve. Thus, if a and b are known:

$$\tan A=\frac{a}{b}$$

$$B=90°-A$$

$$c=a \csc A.$$

Similarly, if c and B are given:

$$A=90°-B$$

$$a=c \sin A$$

$$b=c \cos A.$$

Oblique plane triangles.—In solving an oblique plane triangle, it is often desirable to draw a rough sketch of the triangle approximately to scale, as shown in figure 142a. The following laws are helpful in solving such triangles:

Law of sines: $$\frac{a}{\sin A}=\frac{b}{\sin B}=\frac{c}{\sin C}$$

Law of cosines: $a^2=b^2+c^2-2\,bc \cos A.$

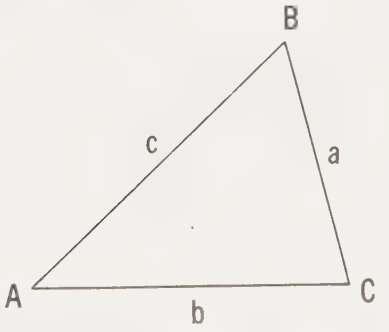

FIGURE 142a.—A plane oblique triangle.

The unknown parts of oblique plane triangles can be computed by the formulas of table 142a, among others. By reassignment of letters to sides and angles, these formulas can be used to solve for all unknown parts of oblique plane triangles.

Known	*To find*	*Formula*	*Comments*
a, b, c	A	$\cos A=\frac{c^2+b^2-a^2}{2bc}$	Cosine law

	c	$c=\frac{a \sin C}{\sin A}$	Sine law

TABLE 142a.—Formulas for solving oblique plane triangles.

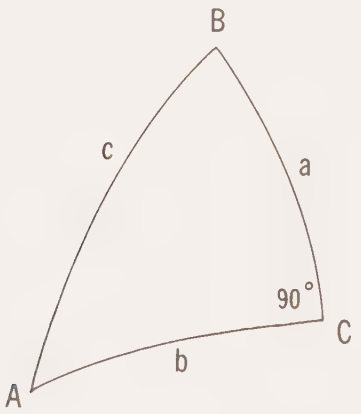

FIGURE 142b.—Parts of a right spherical triangle as used in Napier's rules.

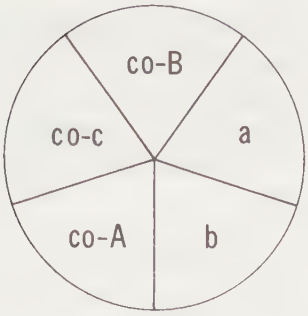

FIGURE 142c.—Diagram for Napier's Rules of Circular Parts.

Right spherical triangles can be solved with the aid of **Napier's Rules of Circular Parts,** devised by John Napier. If the right angle is omitted, the triangle has five parts: two angles and three sides, as shown in figure 142b. The triangle can be solved if any two parts are known. If the two sides forming the right angle, and the *complements* of the other three parts are used, these elements (called "parts" in the rules) can be arranged in five sectors of a circle in the same order in which they occur in the triangle, as shown in figure 142c. Considering *any* part as the *middle* part, the two parts nearest it in the diagram are considered the *adjacent* parts, and the two farthest from it the *opposite* parts. The rules are:

The sine of a middle part equals the product of (1) the tangents of the adjacent parts or (2) the cosines of the opposite parts.

In the use of these rules, the ***co***function of a complement can be given as the function of the element. Thus, the cosine of co-A is the same as the sine of A. From these rules the following formulas can be derived:

$$\sin a = \tan b \cot B = \sin c \sin A$$
$$\sin b = \tan a \cot A = \sin c \sin B$$
$$\cos c = \cot A \cot B = \cos a \cos b$$
$$\cos A = \tan b \cot c = \cos a \sin B$$
$$\cos B = \tan a \cot c = \cos b \sin A.$$

The following rules apply:

1. An oblique angle and the side opposite are in the same quadrant.

2. Side c (the hypotenuse) is less then 90° when a and b are in the same quadrant, and more than 90° when a and b are in different quadrants.

If the known parts are an angle and its opposite side, two solutions are possible.

A **quadrantal spherical triangle** is one having one side of 90°. A **biquadrantal spherical triangle** has two sides of 90°. A **triquadrantal spherical triangle** has three sides of 90°. A biquadrantal spherical triangle is isosceles and has two right angles opposite the 90° sides. A triquadrantal spherical triangle is equilateral, has three right angles, and bounds an octant (one-eighth) of the surface of the sphere. A quadrantal spherical triangle can be solved by Napier's rules provided any two elements in addition to the 90° side are known. The 90° side is omitted and the other parts are arranged in order in a five-sectored circle, using the complements of the three parts farthest from the 90° side. In the case of a quadrantal triangle, rule 1 above is used, and rule 2 restated: angle C (the angle opposite the side of 90°) is *more* than 90° when A and B are in the same quadrant, and *less* than 90° when A and B are in different quadrants. If the

rule requires an angle of more than 90° and the solution produces an angle of less than 90°, subtract the solved angle from 180°.

Oblique spherical triangles.—An oblique spherical triangle can be solved by dropping a perpendicular from one of the apexes to the opposite side, extended if necessary, to form two right spherical triangles. It can also be solved by the following formulas, reassigning the letters as necessary.

Known	*To find*	*Formula*	*Comments*
a, b, c	A	$\text{hav } A=\frac{\text{hav } a-\text{hav } (b-c)}{\sin b \sin c}$

TABLE 142b.—Formulas for solving oblique spherical triangles.

143. Other useful formulas.—In addition to the fundamental trigonometric identities and reduction formulas given in article 140, the following formulas apply to plane and spherical trigonometry:

Addition and Subtraction Formulas

$$\sin(\theta+\phi) = \sin\theta\cos\phi + \cos\theta\sin\phi$$
$$\cos(\theta+\phi) = \cos\theta\cos\phi - \sin\theta\sin\phi$$
$$\sin(\theta-\phi) = \sin\theta\cos\phi - \cos\theta\sin\phi$$
$$\cos(\theta-\phi) = \cos\theta\cos\phi + \sin\theta\sin\phi$$
$$\tan(\theta+\phi) = \frac{\tan\theta+\tan\phi}{1-\tan\theta\tan\phi}.$$

Double-Angle Formulas

$$\sin 2\theta = 2\sin\theta\cos\theta$$
$$\cos 2\theta = \cos^2\theta - \sin^2\theta$$
$$\tan 2\theta = \frac{2\tan\theta}{1-\tan^2\theta}.$$

Half-Angle Formulas

$$\sin\frac{\theta}{2} = \pm\sqrt{\frac{1-\cos\theta}{2}}$$
$$\cos\frac{\theta}{2} = \pm\sqrt{\frac{1+\cos\theta}{2}}$$
$$\tan\frac{\theta}{2} = \pm\sqrt{\frac{1-\cos\theta}{1+\cos\theta}}.$$

The following are useful formulas of spherical trigonometry:

Law of Cosines for Sides

$$\cos a = \cos b\cos c + \sin b\sin c\cos A$$
$$\cos b = \cos c\cos a + \sin c\sin a\cos B$$
$$\cos c = \cos a\cos b + \sin a\sin b\cos C.$$

Law of Cosines for Angles

$$\cos A = -\cos B\cos C + \sin B\sin C\cos a$$
$$\cos B = -\cos C\cos A + \sin C\sin A\cos b$$
$$\cos C = -\cos A\cos B + \sin A\sin B\cos c.$$

Law of Sines

$$\frac{\sin a}{\sin A} = \frac{\sin b}{\sin B} = \frac{\sin c}{\sin C}.$$

Napier's Analogies

$$\tan\tfrac{1}{2}(A+B) = \frac{\cos\frac{1}{2}(a-b)}{\cos\frac{1}{2}(a+b)}\cot\tfrac{1}{2}C \qquad \tan\tfrac{1}{2}(a+b) = \frac{\cos\frac{1}{2}(A-B)}{\cos\frac{1}{2}(A+B)}\tan\tfrac{1}{2}c$$
$$\tan\tfrac{1}{2}(A-B) = \frac{\sin\frac{1}{2}(a-b)}{\sin\frac{1}{2}(a+b)}\cot\tfrac{1}{2}C \qquad \tan\tfrac{1}{2}(a-b) = \frac{\sin\frac{1}{2}(A-B)}{\sin\frac{1}{2}(A+B)}\tan\tfrac{1}{2}c.$$

Five Parts Formulas

$$\sin a\cos B = \cos b\sin c - \sin b\cos c\cos A$$
$$\sin b\cos C = \cos c\sin a - \sin c\cos a\cos B$$
$$\sin c\cos A = \cos a\sin b - \sin a\cos b\cos C.$$

Haversine Formulas

hav a= hav $(b \sim c)$ + sin b sin c hav A hav A= [hav a− hav $(b \sim c)$] csc b csc c
hav b= hav $(a \sim c)$ + sin a sin c hav B hav B= [hav b− hav $(a \sim c)$] csc a csc c
hav c= hav $(a \sim b)$ + sin a sin b hav C hav C= [hav c− hav $(a \sim b)$] csc a csc b.

144. Functions of a small angle.—In figure 144a, small angle θ, measured in radians, is subtended by the arc RR' of a circle. The radius of the circle is r, and $R'P$ is perpendicular to OR at P. Since the length of the arc of a circle is equal to the radius multiplied by the angle subtended in radians,

$$RR' = r \times \theta.$$

When θ is sufficiently small for $R'P$ to approximate RR',

$$\sin \theta = \theta$$

$$\text{since } \theta = \frac{RR'}{r} \text{ and } \sin \theta = \frac{R'P}{r}.$$

For small angles, it can also be shown that

$$\tan \theta = \theta.$$

If there are x minutes of arc (x') in a small angle of θ radians,

$$\sin x' = x \sin 1'.$$

Figure 144a also shows that when θ is small, OP is approximately equal to the radius. Therefore, cos θ can be taken as equal to 1.

Another approximation can be obtained if cos θ is expressed in terms of the half-angle:

$$\cos \theta = 1 - 2 \sin^2 \frac{1}{2} \theta$$

$$\cos \theta = 1 - 2 \left(\frac{1}{2} \theta \right)^2$$

$$\cos \theta = 1 - \frac{1}{2} \theta^2.$$

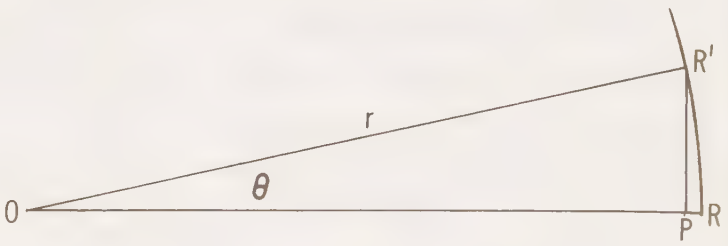

FIGURE 144a.—A small angle.

Calculus

145. Definitions.—Calculus is that branch of mathematics dealing with the rate of change of one quantity with respect to another.

A **constant** is a quantity which does not change. If a vessel is making good a course of 090°, the latitude does not change and is therefore a constant.

A **variable,** where continuous, is a quantity which can have an infinite number of values, although there may be limits to the maximum and minimum. Thus, from latitude 30° to latitude 31° there are an infinite number of latitudes, if infinitesimally small units are taken, but no value is less than 30° nor more than 31°. If two variables are so related that for every value of one there is a corresponding value of the other, one of the values is known as a **function** of the other. Thus, if speed is constant, the distance a vessel steams depends upon the elapsed time. Since elapsed time does not depend upon any other quantity, it is called an **independent variable.** The distance depends

upon the elapsed time, and therefore is called a **dependent variable.** If it is required to find the time needed to travel any given distance at constant speed, distance is the independent variable and time is the dependent variable.

The principal processes of calculus are differentiation and integration.

146. Differentiation is the process of finding the rate of change of one variable with respect to another. If x is an independent variable, y is a dependent variable, and y is a function of x, this relationship may be written $y=f(x)$. Since for every value of x there is a corresponding value of y, the relationship can be plotted as a curve, figure 146. In this figure, A and B are any two points on the curve, a short distance apart.

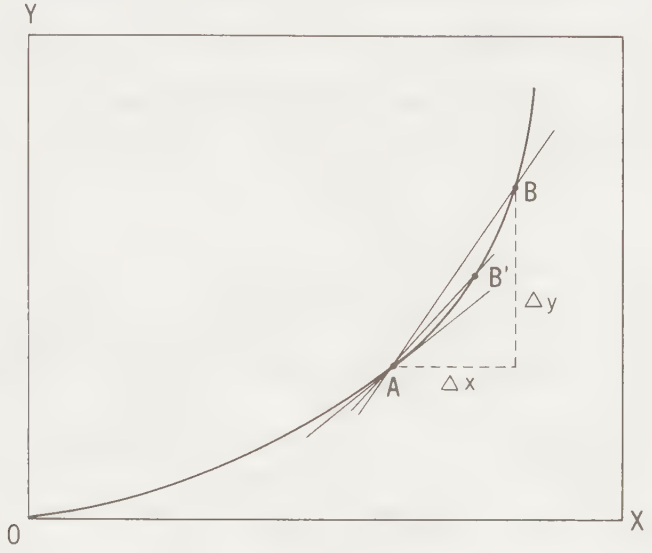

FIGURE 146.—Differentiation.

The difference between the value of x at A and at B is Δx (delta x), and the corresponding difference in the value of y is Δy (delta y). The straight line through points A and B is a **secant** of the curve (art. 130). It represents the rate of change between A and B, for anywhere along this line the change of y is proportional to the change of x.

As B moves closer to A, as shown at B', both Δx and Δy become smaller, but at a different rate, and $\frac{\Delta y}{\Delta x}$ changes. This is indicated by the difference in the slope of the secant. Also, that part of the secant between A and B moves closer to the curve and becomes a better approximation of it. The limiting case occurs when B reaches A or is at an infinitesimal distance from it. As the distance becomes infinitesimal, both Δy and Δx become infinitely small, and are designated dy and dx, respectively. The straight line becomes tangent to the curve, and represents the rate of change, or slope, of the curve at that point. This is indicated by the expression $\frac{dy}{dx}$, called the **derivative** of y with respect to x.

The process of finding the value of the derivative is called **differentiation.** It depends upon the ability to connect x and y by an equation. For instance, if $y=x^n$, $\frac{dy}{dx}=nx^{n-1}$. If $n=2$, $y=x^2$, and $\frac{dy}{dx}=2x$. This is derived as follows: If point A on the

curve is x, y; point B can be considered $x+\Delta x$, $y+\Delta y$. Since the relation $y=x^2$ is true anywhere on the curve, at B:

$$y+\Delta y=(x+\Delta x)^2=x^2+2x\Delta x+(\Delta x)^2.$$

Since $y=x^2$, and equal quantities can be subtracted from both sides of an equation without destroying the equality:

$$\Delta y=2x\Delta x+(\Delta x)^2.$$

Dividing by Δx:

$$\frac{\Delta y}{\Delta x}=2x+\Delta x.$$

As B approaches A, Δx becomes infinitesimally small, approaching 0 as a limit Therefore $\frac{\Delta y}{\Delta x}$ approaches $2x$ as a limit.

This can be demonstrated by means of a numerical example. Let $y=x^2$. Suppose at A, $x=2$ and $y=4$, and at B, $x=2.1$ and $y=4.41$. In this case $\Delta x=0.1$ and $\Delta y=0.41$, and

$$\frac{\Delta y}{\Delta x}=\frac{0.41}{0.1}=4.1.$$

From the other side of the equation:

$$2x+\Delta x=2\times 2+0.1=4.1.$$

If Δx is 0.01 and Δy is 0.0401, $\frac{\Delta y}{\Delta x}=4.01$. If Δx is 0.001, $\frac{\Delta y}{\Delta x}=4.001$; and if Δx is 0.0001, $\frac{\Delta y}{\Delta x}=4.0001$. As Δx approaches 0 as a limit, $\frac{\Delta y}{\Delta x}$ approaches 4, which is therefore the value $\frac{dy}{dx}$. Therefore, at point A the *rate* of change of y with respect to x is 4, or y is increasing in value 4 times as fast as x.

An example of the use of differentiation in navigation is the Δd value in Pub. No. 214. This is the change of altitude for a change of 1′ of declination. In this case, declination is the independent variable, altitude is the dependent variable, and both meridian angle (H.A.) and latitude are constants. The rate of change at the tabulated value is desired, so that the table can be entered with the *nearest* tabulated value of declination, and interpolation performed in either direction (either larger or smaller values of declination).

147. Integration is the inverse of differentiation. Unlike the latter, however, it is not a direct process, but involves the recognition of a mathematical expression as the differential of a known function. The function sought is the **integral** of the given expression. Most functions can be differentiated, but many cannot be integrated.

Integration can be considered the summation of an infinite number of infinitesimally small quantities, between specified limits. Consider, for instance, the problem of finding an area below a specified part of a curve for which a mathematical expression can be written. Suppose it is desired to find the area *ABCD* of figure 147. If vertical lines are drawn dividing the area into a number of vertical strips, each Δx wide, and if y is the height of each strip at the midpoint of Δx, the area of each strip is approximately $y\Delta x$; and the approximate total area of all strips is the sum of the areas of the individual strips. This may be written $\sum_{x_1}^{x_2} y\Delta x$, meaning the sum of all y Δx values between x_1 and x_2. The symbol $\sum$ is the Greek letter *sigma*, the equivalent of the English *S*.

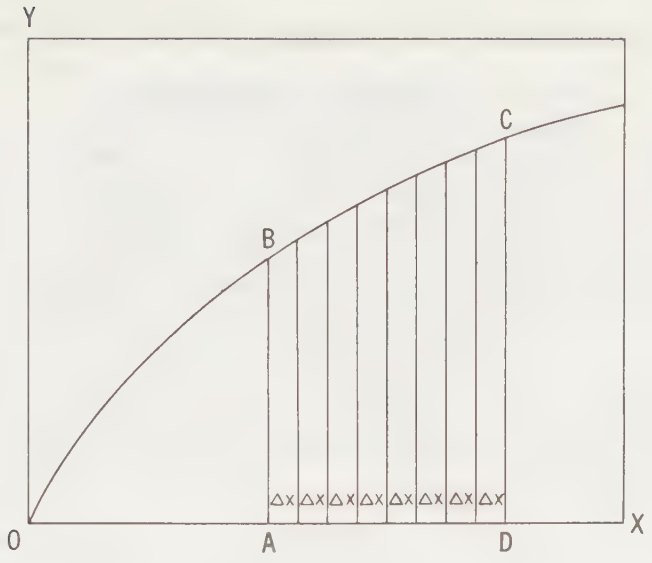

FIGURE 147.—Integration.

If Δx is made progressively smaller, the sum of the small areas becomes ever closer to the true total area. If Δx becomes infinitely small, the summation expression is written $\int_{x_1}^{x_2} y dx$, the symbol dx denoting an infinitely small Δx. The symbol $\int$, called the "integral sign," is a distorted S.

An expression such as $\int_{x_1}^{x_2} y dx$ is called a **definite integral** because limits are specified (x_1 and x_2). If limits are not specified, as in $\int y dx$, the expression is called an **indefinite integral.**

A navigational application of integration is the finding of meridional parts, table 5. The *rate* of change of meridional parts with respect to latitude changes progressively. The formula given in the explanation of the table is the equivalent of an integral representing the sum of the meridional parts from the equator to any given latitude.

148. Differential equations.—An expression such as dy or dx is called a **differential.** An equation involving a differential or a derivative is called a **differential equation.**

As shown in article 146, if $y=x^2$, $\frac{dy}{dx}=2x$. Neither dy nor dx is a finite quantity, but both are *limits* to which Δy and Δx approach as they are made progressively smaller. Therefore $\frac{dy}{dx}$ is merely a ratio, the limiting value of $\frac{\Delta y}{\Delta x}$, and not one finite number divided by another. However, since the ratio is the same as would be obtained by using finite quantities, it is possible to use the two differentials dy and dx independently in certain relationships. Differential equations involve such relationships.

Other examples of differential equations are:

$d \sin x = \cos x\, dx$
$d \cos x = -\sin x\, dx$
$d \tan x = \sec^2 x\, dx$
$d \csc x = -\cot x \csc x\, dx$
$d \sec x = \tan x \sec x\, dx$
$d \cot x = -\csc^2 x\, dx.$

Some differential equations indicating the variations in the astronomical triangle are:

$$dh = -\cos L \sin Z\, dt;\ L \text{ and } d \text{ constant}$$
$$dh = \cos Z\, dL;\ d \text{ and } t \text{ constant}$$
$$dh = -\cos h \tan M\, dZ;\ L \text{ and } d \text{ constant}$$
$$dZ = -\sec L \cot t\, dL;\ d \text{ and } h \text{ constant}$$
$$dZ = \tan h \sin Z\, dL;\ d \text{ and } t \text{ constant}$$
$$dt = -\sec L \cot Z\, dL;\ d \text{ and } h \text{ constant}$$
$$dZ = \cos d \sec h \cos M\, dt;\ L \text{ and } d \text{ constant}$$
$$dd = \cos d \tan M\, dt;\ L \text{ and } h \text{ constant}$$
$$dd = \cos L \sin t\, dZ;\ L \text{ and } h \text{ constant},$$

where h is the altitude, L is the latitude, Z is the azimuth angle, d is the declination, t is the meridian angle, and M is the parallactic angle.

CHAPTER II

INTERPOLATION

201. Introduction.—If one quantity varies with changing values of a second quantity, and the mathematical relationship of the two is known, a curve can be drawn to represent the values of one corresponding to various values of the other. To find the value of either quantity corresponding to a given value of the other, one finds that point on the curve defined by the given value, and reads the answer on the scale relating to the other quantity. This assumes, of course, that for each value of one quantity, there is only one value of the other quantity.

Information of this kind can also be tabulated. Each entry represents one point on the curve. The finding of a value *between* tabulated entries is called **interpolation.** The extending of tabulated values to find values *beyond* the limits of the table is called **extrapolation.**

Thus, the *Nautical Almanac* tabulates values of declination of the sun for each hour of Greenwich mean time. The finding of declination for a time between two whole hours requires interpolation. Since there is only one entering **argument** (in this case GMT), **single interpolation** is involved.

Table 19 gives the distance traveled in various times at certain speeds. In this table there are two entering arguments. If both given values are between tabulated values, **double interpolation** is needed.

In Pub. No. 214, azimuth angle varies with a change in any of the three variables latitude, declination, and meridian angle. With intermediate values of all three, **triple interpolation** is needed.

Interpolation can sometimes be avoided. A table having a single entering argument can be arranged as a **critical table.** An example is the dip (height of eye) correction on the inside front cover of the *Nautical Almanac*. Interpolation is avoided through dividing the argument into intervals so chosen that successive intervals correspond to successive values of the required quantity, the respondent. For any value of the argument within these intervals, the respondent can be extracted from the table without interpolation. The lower and upper limits (critical values) of the argument correspond to half-way values of the respondent and, by convention, are chosen so that when the argument is equal to one of the critical values, the respondent corresponding to the preceding (upper) interval is to be used. Another way of avoiding interpolation would be to include every possible entering argument. If this were done for Pub. No. 214, interpolation being eliminated for declination only, and assuming declination values to 0′.1, the number of volumes would be increased from nine to more than 5,000. If interpolation for meridian angle and latitude, to 0′.1, were also to be avoided, a total of more than 1,800,000,000 volumes would be needed. A more practical method is to select an assumed position to avoid the need for interpolation for two of the variables.

202. Single interpolation.—The accurate determination of intermediate values requires knowledge of the nature of the change between tabulated values. The simplest relationship is **linear,** the change in the tabulated value being directly proportional to

the change in the entering argument. Thus, if a vessel is proceeding at 15 knots, the distance traveled is directly proportional to the time, as shown in figure 202a. The same information might be given in tabular form, as shown in table 202a. Mathematically, this relationship for 15 knots is written $D=\frac{15t}{60}=\frac{t}{4}$, where D is distance in nautical miles, and t is time in minutes.

In such a table, interpolation can be accomplished by simple proportion. Suppose, for example, that the distance is desired for a time of 15 minutes. It will be some

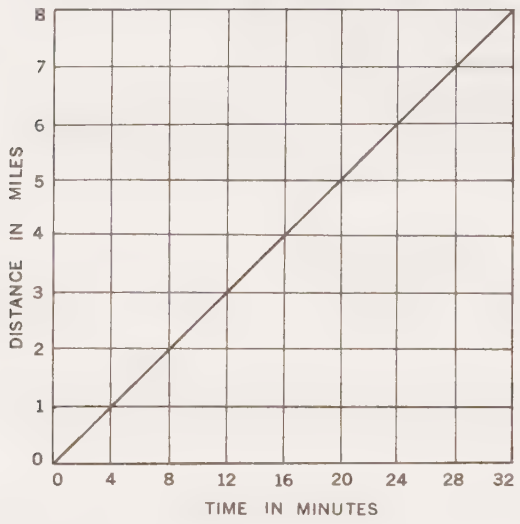

FIGURE 202a.—Plot of $D=\frac{t}{4}$.

Minutes	*Miles*
0	0.0
4	1.0
8	2.0
12	3.0
16	4.0
20	5.0
24	6.0
28	7.0
32	8.0

TABLE 202a.—Table of $D=\frac{t}{4}$.

value between 3.0 and 4.0 miles, because these are the distances for 12 and 16 minutes, respectively, the tabulated times on each side of the desired time. The proportion might be formed as follows:

$$3\left[\begin{matrix}12\\15\\16\end{matrix}\right]4 \qquad\qquad x\left[\begin{matrix}3.0\\y\\4.0\end{matrix}\right]1.0$$

$$\frac{3}{4}=\frac{x}{1.0}$$

$$x=\frac{3\times 1.0}{4}=0.75 \text{ (0.8 to nearest 0.1 mi.)}$$

$$y=3.0+x=3.0+0.8=3.8 \text{ mi.}$$

A simple interpolation such as this should be performed mentally. During the four-minute interval between 12 and 16 minutes, the distance *increases* 1.0 mile from 3.0 to 4.0 miles. At 15 minutes, ¾ of the interval has elapsed, and so the distance increases ¾ of 1.0 mile, or 0.75 mile, and is therefore 3.0+0.8=3.8, to the nearest 0.1 mile.

This might also have been performed by starting with 16 minutes, as follows:

$$1\left[\begin{array}{r}12\\15\\16\end{array}\right]4 \qquad (-)x\left[\begin{array}{r}3.0\\y\\4.0\end{array}\right]1.0$$

$$\frac{1}{4}=\frac{(-)x}{1.0}$$

$$x=(-)0.25\ (-0.2 \text{ to the nearest } 0.1 \text{ mi.})$$

$$y=4.0-0.2=3.8$$

Mentally, 15 is one quarter of the way from 16 to 12, and therefore the distance is ¼ the way between 4.0 and 3.0, or 3.8.

This interpolation might have been performed by noting that if distance changes 1.0 mile in four minutes, it must change $\frac{1.0}{10}=0.1$ mile in $\frac{4}{10}=0.4$ minute, or 24 seconds. This relationship can be used for mental interpolation in situations which might seem to require pencil and paper. Thus, if distance to the nearest 0.1 mile is desired for 13^m15^s, the answer is 3.3 miles, determined as follows: The time 13^m15^s is 1^m15^s (1^m2 approx.) more than 12^m. If 1.2 is divided by 0.4, the quotient is 3, to the nearest whole number. Therefore, $3\times0.1=0.3$ is added to 3, the tabulated value for 12 minutes. Alternatively, 13^m15^s is 2^m45^s (2^m8 approx.) less than 16^m, and $2.8\div0.4=7$, and therefore the interpolated value is $7\times0.1=0.7$ *less* than 4, the tabulated value for 16^m. In either case, the interpolated value is 3.3 miles.

A common mistake in single interpolation is to apply the correction (x) with the wrong sign, particularly when it should be negative (—). This mistake can be avoided by always checking to be certain that the interpolated value lies between the two values used in the interpolation.

When the curve representing the values of a table is a straight line, as in figure 202a, the process of finding intermediate values in the manner described above is called **linear interpolation.** If tabulated values of such a line are exact (not approximations), as in table 202a, the interpolation can be carried to any degree of precision without sacrificing accuracy. Thus, in 21.5 minutes the distance is $5.0+\frac{1.5}{4}\times1.0=5.375$ miles. Similarly, for 29.9364 minutes the distance is $7.0+\frac{1.9364}{4}\times1.0=7.4841$ miles, a value which has little or no significance in practical navigation. If one had occasion to find such a value, it could most easily be done by dividing the time, in minutes, by 4, since the distance increases at the rate of one mile each four minutes. This would be a case of avoiding interpolation by solving the equation connecting the two quantities. For a simple relationship such as that involved here, such a solution might be easier than interpolation.

Many of the tables of navigation are not linear. Consider figure 202b. From table 29 it is found that for latitude 25° and declination 8°, same name, the variation of altitude in one minute of time from meridian transit (the altitude factor) is 6′.0 (0′.1). For a limited angular distance on each side of the celestial meridian, the change in altitude is approximately equal to at^2, where a is the altitude factor (from table 29) and t is the time in minutes from meridian transit. Figure 202b is the plot of change in altitude against time. The same information is shown in tabular form in table 202b.

To be strictly accurate in interpolating in such a table, one should consider the curvature of the line. However, in most navigational tables the points on the curve selected for tabulation are sufficiently close that the portion of the curve between entries can be considered a straight line without introducing a significant error. This is similar to considering the line of position from a celestial observation as a part of the circle of equal altitude. Thus, to the nearest 0′.1, the change of altitude for 3.4 minutes is $0'.9+(0.4\times0'.7)=0'.9+0'.3=1'.2$. The correct value by solution of the formula is 1′.156. The value for 6.8 minutes is 4′.6 by interpolation and 4′.624 by computation.

If the *direction* of curvature of the curve changes between entering arguments, an erroneous result might be obtained. Thus, in Pub. No. 214, the tabulated altitude for latitude 53° and meridian angle 0° is 89°30′.0 for declination 52°30′ same name, and

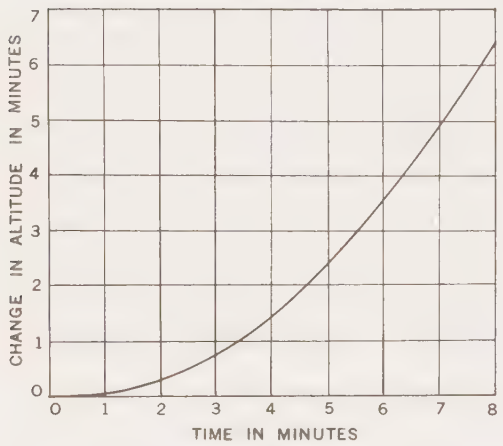

FIGURE 202b.—Plot of altitude change$=at^2$.

Minutes	*Altitude change*

6	3.6
7	4.9
8	6.4

TABLE 202b.—Table of altitude change$=at^2$, where $a=0'.1$.

89°00′.0 for declination 54°00′ same name, the next entry. By linear interpolation for declination 53° same name the altitude is 89°20′.0. The correct value is 90°00′.0. Between declination 52°30′ and 53°00′ the altitude increases to 90°00′.0 and then decreases as declination increases. Such instances are infrequent in navigation, and generally occur at a part of the table that is not commonly used, or for which special provisions are made.

203. Double interpolation.—In a double-entry table it may be necessary to interpolate for each entering argument. Table 203a is an extract from table 27 (amplitudes). If one entering argument is an exact tabulated value, the amplitude can be found by single interpolation. For instance, if latitude is 45° and declination is 21°.8, amplitude is $31°.2+\left(\frac{3}{5}\times0°.8\right)=31°.2+0°.5=31°.7$. However, if neither entering argument is a tabulated value, double interpolation is needed. This may be accomplished in any of several ways:

Lat.	*Declination*	
	21°.5	22°.0
°	°	°
45	31.2	32.0
46	31.8	32.6

TABLE 203a.—Excerpts from amplitude table.

1. *"Horizontal" method.* Use single interpolation for declination for each tabulated value of latitude, followed by single interpolation for latitude. Suppose latitude is

45°.7 and declination is 21°.8. First, find the amplitude for latitude 45°, declination 21°.8, as above, 31°.7. Next, repeat the process for latitude 46°: $31°.8+\left(\frac{3}{5}\times 0°.8\right)=32°.3$. Finally, interpolate between 31°.7 and 32°.3 for latitude 45°.7: $31°.7+(0.7\times 0°.6)=32°.1$. This is the equivalent of first inserting a new column for declination 21°.8, followed by single interpolation in this column, as shown in table 203b.

Lat.	*Declination*		
	21°.5	*21°.8*	22°.0
°	°	°	°
45	31.2	*31.7*	32.0
45.7		***32.1***	
46	31.8	*32.3*	32.6

TABLE 203b.—"Horizontal" method of double interpolation.

Lat.	*Declination*		
	21°.5	*21°.8*	22°.0
°	°	°	°
45	31.2		32.0
45.7	*31.6*	***32.1***	*32.4*
46	31.8		32.6

TABLE 203c.—"Vertical" method of double interpolation.

2. *"Vertical" method.* Use single interpolation for latitude for each tabulated value of declination, followed by single interpolation for declination. Consider the same example as above. First, find the amplitude for declination 21°.5, latitude 45°.7: $31°.2+(0°.7\times 0°.6)=31°.6$. Next, repeat the process for declination 22°.0: $32°.0+(0°.7\times 0°.6)=32°.4$. Finally, interpolate between 31°.6 and 32°.4 for declination 21°.8: $31°.6+\left(\frac{3}{5}\times 0°.8\right)=32°.1$. This is the equivalent of first inserting a new line for latitude 45°.7, followed by single interpolation in this line, as shown in table 203c.

3. *Combined method.* Select a tabulated "base" value, preferably that nearest the given tabulated entering arguments. Next, find the correction to be applied, with its sign, for single interpolation of this base value both horizontally and vertically. Finally, add these two corrections algebraically and apply the result, in accordance with its sign, to the base value. In the example given above, the base value is 32°.6, for declination 22°.0 (21°.8 is nearer 22°.0 than 21°.5) and latitude 46° (45°.7 is nearer 46° than 45°). The correction for declination is $\frac{2}{5}\times(-)0°.8=(-)0°.3$. The correction for latitude is $0°.3\times(-)0°.6=(-)0°.2$. The algebraic sum is $(-)0°.3+(-)0°.2=(-)0°.5$. The interpolated value is then $32°.6-0°.5=32°.1$. This is the method customarily used by navigators.

204. Triple interpolation.—With three entering arguments, the process is similar to that for double interpolation. It would be possible to perform double interpolation for the tabulated value on each side of the given value of one argument, and then interpolate for that argument, but the method would be tedious. The only method commonly used by navigators is that of selecting a base value and applying corrections. Suppose, for instance, that the azimuth angle is desired for latitude 41°.3, declination 21°.9 contrary name, meridian angle 16°.6 using Pub. No. 214. The base value (lat. 41°, Dec. 22°, t 17°) is 162°.6. The corrections are

lat.	41°.3: 0.3 × (+) 0°.1 =	0°.0
Dec.	21°.9: 0.2 × (−) 0°.1 =	0°.0
t	16°.6: 0.4 × (+) 1°.0 =	(+) 0°.4
	Total	(+) 0°.4.

The triple interpolated value is 162°.6+0°.4=163°.0

205. Nonlinear interpolation.—When the curve representing the values of a table is nearly a straight line, or the portion of the curve under consideration is nearly a straight line, linear interpolation suffices. However, when the successive tabular values are so nonlinear that a portion of the curve under consideration is not a close approximation of a straight line, it is necessary to include the effects of second differences, and possibly higher differences, as well as first differences in the interpolation.

The plot of table 205a data in figure 205 indicates that the altitude does not change linearly between declination values of 51° and 52°. If the first difference only were used in the interpolation, the interpolated value of altitude would lie on the straight line between points on the curve for declination values of 51° and 52°.

TABLE 205b.—Notation used with Bessel's formula.

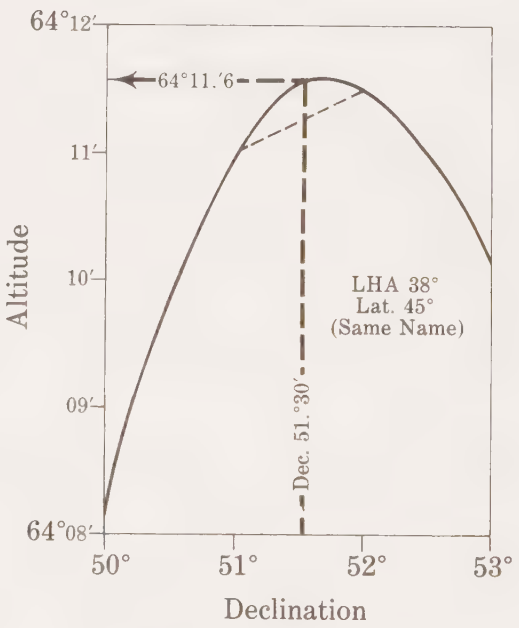

FIGURE 205.—Altitude curve.

If the altitude for declination 51°30′ is obtained using only the **first difference,** i.e., the difference between successive tabular altitudes in this case, $Hc=64°11'.0+\frac{30'}{60'}\times 0'.5=64°11'.3$. However, inspection of figure 205 reveals that this interpolated altitude

is 0′.3 low. If the tabular data were such that the differences between successive first differences, the **second differences,** were nearly zero, interpolation using the first difference only would provide the correct altitude. In this case, however, second differences are significant and must be included in the interpolation.

Table 205b shows the format and notation used to distinguish the various tabular quantities and differences when using Bessel's formula for the nonlinear interpolation. The quantities f_{-2}, f_{-1}, f_o, f_1, f_2, f_3 represent successive tabular values.

Allowing for first and second differences only, Bessel's formula is stated as:

$$f_p = f_o + p\Delta'_{1/2} + B''(\Delta''_o + \Delta''_1),$$

In this case, f_p is the computed altitude; f_o is the tabular altitude; p is the fraction of the interval between tabular values of declination. The quantity B″ is a function of p and is always negative. This Besselian Coefficient is tabulated in Table XIII of *The American Ephemeris and Nautical Almanac*. The quantity $(\Delta''_o + \Delta''_1)$ is the **double second difference** (**DSD**), which is the sum of successive second differences.

Applying Bessel's formula to the data of table 205a to obtain the altitude for a declination of 51°30′,

$$f_p = f_0 + p\Delta'_{1/2} + B''\,(\Delta''_0 + \Delta''_1)$$

$$Hc = 64°11'.0 + \frac{30'}{60'}\,(0'.5) + (-0.062)\,[-2'.3 + (-2'.1)]$$

$$Hc = 64°11'.0 + 0'.3 + 0'.3 = 64°11'.6.$$

206. Interpolation tables.—A number of frequently used navigation tables are provided with auxiliary tables to assist in interpolation. Table 32 (Logarithms of Numbers) provides columns of "d" (difference between consecutive entries) and auxiliary "proportional parts" tables. The auxiliary table for the applicable difference "d" is selected and entered with the digit of the additional place in the entering argument. The value taken from the auxiliary table is *added* to the base value for the next *smaller* number from the main table. Suppose the logarithm (mantissa) for 32747 is desired. The base value for 3274 is 51508, and "d" is 13. The auxiliary table for 13 is entered with 7, and the correction is found to be 9. If this is added to 51508, the interpolated value is found to be 51517. This is the same result that would be obtained by subtracting 51508 from 51521 (the logarithm for 3275) to obtain 13, multiplying this by 0.7, and adding the result (9) to 51508.

Tables 31 and 33 provide the difference between consecutive entries, but no proportional parts tables.

The *Nautical Almanac* "Increments and Corrections" are interpolation tables for the hourly entries of GHA and declination. The increments are the products of the constant value used as the change of GHA in 1 hour and the fractional part of the hour. The corrections provide for the difference between the actual change of GHA in 1 hour and the constant value used. The corrections also provide the product of the change in declination in 1 hour and the fractional part of the hour.

The main part of the four-page interpolation table of Pub. No. 229 is basically a multiplication table providing tabulations of:

$$\text{Altitude Difference} \times \frac{\text{Declination Increment}}{60'}.$$

The design of the table is such that the desired product must be derived from component parts of the altitude difference. The first part is a multiple of 10′ (10′, 20′, 30′, 40′, or 50′) of the altitude difference; the second part is the remainder in the range 0′.0 to 9′.9. For example, the component parts of altitude difference 44′.3 are 40′ and 4′.3.

In the use of the first part of the altitude difference, the table arguments are declination increment (Dec. Inc.) and the integral multiple of 10′ in the altitude difference, d. As shown in figure 206a, the respondent is:

$$\text{Tens} \times \frac{\text{Dec. Inc.}}{60'}.$$

In the use of the second part of the altitude difference, the interpolation table arguments are the nearest Dec. Inc. ending in 0′.5 and Units and Decimals. The respondent is:

$$\text{Units and Decimals} \times \frac{\text{Dec. Inc.}}{60'}.$$

In computing the table, the values in the Tens part of the multiplication table were modified by small quantities varying from −0′.042 to +0′.033 before rounding to the tabular precision to compensate for any difference between the actual Dec. Inc. and the nearest Dec. Inc. ending in 0′.5 when using the Units and Decimals part of the table.

INTERPOLATION TABLE

Dec. Inc.	Altitude Difference (d)															Double Second Diff. and Corr.
	Tens					Decimals	Units									
	10′	20′	30′	40′	50′		0′	1′	2′	3′	4′	5′	6′	7′	8′	9′	
45.0						.0										18.1 0.8
45.1						.1										20.3 0.9
45.2	Tens × Dec. Inc. / 60′					.2	Units & Decimals × Dec. Inc. / 60′									22.4 1.0

45.6						.6										30.9 1.4
45.7						.7										33.1 1.5
45.8	40′ × 45′.5 / 60′ = 30′.3					.8	4′.3 × 45′.5 / 60′ = 3′.3									35.2 1.6
45.9						.9										

FIGURE 206a.—Interpolation table.

Using the interpolation table shown in figure 206b to obtain the altitude for 51°30′ from the data of table 205a, the linear correction for the first difference (+0′.5) is +0′.3. This correction is extracted from the Units and Decimals block opposite the Dec. Inc. (30′.0). The correction for the double second difference (DSD) is extracted from the DSD subtable opposite the block in which the Dec. Inc. is found. The argument for entering this critical table is the DSD (−4′.4). The DSD correction is +0′.3. Therefore,

$$\begin{aligned} Hc &= ht + \text{first difference correction} + \text{DSD correction} \\ &= 64°11'.0 + 0'.3 + 0'.3 = 64°11'.6. \end{aligned}$$

FIGURE 206b.—Interpolation table.

207. Extrapolation.—The extending of a table is usually performed by assuming that the difference between the last few tabulated entries will continue at the same rate. This assumption is strictly correct only if the change is truly linear, but in most tables the assumption provides satisfactory results for a *slight* extension beyond tabulated values. The extent to which the assumption can be used reliably can often be determined by noting the last few differences. If the "second differences" (differences between consecutive differences) are nearly zero, the curve is nearly a straight line, for a short distance. But if consecutive second differences are appreciable, extrapolation is not reliable. For examples of linear and nonlinear relationships, refer to the first page of table 33 and compare the tabulated differences of the logarithms of secant (approximately linear on this page) and sine (nonlinear on this page).

As an example of extrapolation, consider table 27. Suppose the amplitude for latitude 45°, declination 24°.3 is desired. The last declination entry is 24°.0. The amplitude for declination 23°.5 is 34°.3, and for declination 24°.0 it is 35°.1. The difference is (+) 0°.8. Assuming this same difference between declinations 24°.0 and 24°.5, one finds the value for 24°.3 is $35°.1+\left(\frac{3}{5}\times 0°.8\right)=35°.6$. Below latitude 50° this table is so nearly linear that extrapolation can be carried to declination 30° without serious error.

For double or triple extrapolation, differences are found as in single interpolation.

208. General comments.—As a general rule, the final answer should not be given to greater precision than tabulated values. A notable exception to this rule is the case where tabulated values are known to be exact, as in table 202a. A slight increase in accuracy can sometimes be attained by retaining one additional place in the solution until the final answer. Suppose, for instance, that the corrections for triple interpolation are (+)0.2, (+)0.3, and (−)0.3. The total correction is (+)0.2. If the total correction, rounded to tenths, had been obtained from the sum of (+)0.17, (+)0.26, and (−)0.34, the correct total would have been (+)0.09=(+)0.1. The retaining of one additional place may be critical if the correction factors end in 0.5. Thus, in double interpolation, one correction value might be (+)0.15, and the other (−)0.25. The correct total is (−)0.1. But if the individual differences are rounded to (+)0.2 and (−)0.2, the total is 0.0.

The difference used for establishing the proportion is also a matter subject to some judgment. Thus, if the latitude is 17°14′.6, it might be rounded to 17°.2 for many purposes. Slightly more accurate results can sometimes be obtained by retaining the minutes, using $\frac{14.6}{60}$ instead of 0.2. If the difference to be multiplied by this proportion is small, the increase in accuracy gained by using the more exact value is small, but if the difference is large, the gain might be considerable. Thus, if the difference is 0°.2, the correction by using either $\frac{14.6}{60}$ or 0.2 is less than 0°.05, or 0°.0 to the nearest 0°.1. But if the difference is 3°.2, the value by $\frac{14.6}{60}$ is 0°.8, and the value by 0.2 is 0°.6.

If the tabulated entries involved in an interpolation are all positive or all negative, the interpolation can be carried out on either a numerical or an algebraic basis. Most navigators prefer the former, carrying out the interpolation as if all entries were positive, and giving to the interpolated value the common sign of all entries. When both positive and negative entries are involved, all differences and corrections should be on an algebraic basis, and careful attention should be given to signs. Thus, if single interpolation is to be performed between values of (+)0.9 and (−)0.4, the difference is $0.9-(-0.4)=0.9+0.4=1.3$. If the correction is 0.2 of this difference, it is (−)0.3 if applied to (+)0.9, and (+)0.3 if applied to (−)0.4. In the first case, the interpolated value is $(+)0.9-0.3=(+)0.6$. In the second case, it is $(-)0.4+0.3=(-)0.1$. If the correction had been 0.4 of the difference, it would have been (−)0.5 in the first case, and (+)0.5 in the second. The interpolated value would have been $(+)0.9-0.5=(+)0.4$, or $(-)0.4+0.5=(+)0.1$, respectively.

Because of the variety in methods of interpolation used, solutions by different persons may differ slightly.

CHAPTER III

NAVIGATIONAL ERRORS

301. Introduction.—As commonly practiced, navigation is not an exact science. A number of approximations which would be unacceptable in careful scientific work are used by the navigator, because greater accuracy may not be consistent with the requirements or time available, or because there is no alternative.

Thus when the navigator uses his latitude graduations as a mile scale, or computes a great-circle course and distance, he neglects the flattening of the earth at the poles, a practice that is not acceptable to the geodetic surveyor. When the navigator plots a visual bearing, or an azimuth line for a celestial line of position, on a Mercator chart, he uses a rhumb line to represent a great circle. When he plots the celestial line of position, he substitutes a rhumb line for a small circle. When he interpolates in tables of logarithms or in Loran tables, he assumes a linear (constant-rate) change between tabulated values. When he measures distance by radar, or depth by sonic depth finder, he assumes that the radio- or sound-wave has constant speed under all conditions. When he applies dip and refraction corrections to his sextant altitude, he generally assumes standard atmospheric conditions.

These are only a few of the approximations commonly applied by a navigator. There are so many that there is a natural tendency for some of them to cancel others. Thus, under favorable conditions, a position at sea, determined from celestial observation by an experienced observer, should seldom be in error by more than two miles. However, if the various small errors in a particular observation all have the same sign (all plus or all minus), the error might be several times this amount, without any mistake having been made by the navigator.

Greater accuracy could be attained, but at a price. The navigator is a practical individual. In the course of ordinary navigation, he would rather spend ten minutes determining a position having a probable error of plus or minus two miles, than to spend several hours learning where he *was* to an accuracy of a few yards. But if he can determine a recent or present position to greater accuracy, the decrease in error is attractive to him. The various navigational aids have been designed with this in mind. Greater accuracy in plotting could be achieved by increasing the scale of the chart or plotting sheet. This has been done for confined waters where a higher degree of accuracy is needed, but a large-scale plotting sheet would be a nuisance at sea. The hand-held marine sextant is not sufficiently accurate for use in determining an astronomical position in a geodetic survey. But it is much more satisfactory at sea than the surveyor's astrolabe or theodolite, which require stable platforms if their potential accuracy is to be realized.

An understanding of the kinds of errors involved in navigation, and of the elementary principles of probability, should be of assistance to a navigator in interpreting his results.

302. Definitions.—The following definitions apply to the discussions of this chapter:

Error is the difference between a specific value and the correct or standard value. As here used, it does not include mistakes, but is related to lack of perfection. Thus, an

altitude determined by marine sextant is corrected for a standard amount of refraction, but if the actual refraction at the time of observation varies from the standard, the value taken from the table is in error by the difference between standard and actual refraction. This error will be compounded with others in the observed altitude. Similarly, depth determined by echo sounder is in error, among other things, by the difference between the actual speed of sound waves in the water and the speed used for calibration of the instrument. The depth will also be in error if an echo is returned from a phantom bottom instead of from the actual bottom. This chapter is concerned primarily with the deviation from standards. Thus, while variation of the compass is an error when referred to true directions, the difference between the assumed variation and that actually existing is an error with reference to magnetic direction. Corrections can be applied for standard values of error. It is the deviation from standard, as well as mistakes, that produce inaccurate results in navigation. Various kinds of error are discussed in the following articles.

Mistake is a blunder, such as an incorrect reading of an instrument, the taking of a wrong value from a table, or the plotting of a reciprocal bearing.

Standard is something established by custom, agreement, or authority as a basis for comparison. It is customary to use nautical miles for measuring distances between ports. By international agreement the nautical mile is defined as exactly 1852 meters. By authority of various countries which are parties to the agreement, this length is translated to the linear units adopted by that country. It is the fact of establishment or general acceptance that determines whether a given quantity or condition has become a standard of measure or quality. Thus, in 1960, the standard unit of length agreed upon at the Eleventh General (International) Conference on Weights and Measures to redefine the meter was 1,650,763.73 wavelengths of the orange-red radiation in vacuum of krypton 86 corresponding to the unperturbed transition between the $2p_{10}$ and $5d_5$ levels. Where accepted, this established standard of length now serves as a basis for measurement of any physical magnitude, as the length of the meridian, rather than the reverse, which was originally proposed. Multiples and submultiples of a standard are exact. In 1959, the U.S. adopted the exact relationships of one yard as equal to 0.9144 meter and one inch as equal to 2.54 centimeters. Hence, 39.37 U.S. inches are approximately equal to one meter. Because one foot equals 12 inches by definition, and the international nautical mile has been defined as 1852 meters, the international nautical mile is equal to 6,076.11549 U.S. feet (approximately). The previous U.S. foot (6,076.10333 . . . feet equals one nautical mile) has been redesignated as the U.S. survey foot.

Frequently, a standard is so chosen that it serves as a model which approximates a mean or average condition. However, the distinction between the standard value and the actual value at any time should not be forgotten. Thus, a standard atmosphere has been established in which the temperature, pressure, density, etc., are *precisely* specified for each altitude. Actual conditions, however, are generally different from those defined by the standard atmosphere. Similarly, the values for dip given in the almanacs are considered standard by those who use them, but actual dip may be appreciably different from that tabulated.

Accuracy is the degree of conformance with the correct value, while **precision** is the degree of refinement of a value. Thus, an altitude determined by marine sextant might be stated to the nearest 0′.1, and yet be accurate only to the nearest 1′ if the horizon is indistinct. Accuracy and precision are further discussed in article 103.

303. Systematic errors are those which follow some law by which they can be predicted. The accuracy with which a systematic error can be predicted depends upon the accuracy with which the governing law is understood. An error which can be predicted can be eliminated, or compensation can be made for it.

The simplest form of systematic error is one of unchanging magnitude and sign. This is called a **constant error.** Examples are the index error of a marine sextant, watch error, or the error resulting from a lubber's line not being accurately aligned with the longitudinal axis of the craft. In each of these cases, all readings are in error by a constant amount *as long as the adjustment remains unchanged,* and can be removed by applying a correction of equal magnitude and opposite sign. Index error and watch error can be removed by adjustment of the instrument. Lubber's line error can be removed by aligning the lubber's line with the longitudinal axis of the craft.

Another type of systematic error results from a nonstandard rate. If a watch is gaining four seconds per day, its readings will be in error by one second after an interval of six hours, eight seconds at the end of two days, etc. This principle is used in establishing a chronometer rate (art. 608) for determination of chronometer error between comparisons of the chronometer with time signals. It can be eliminated by adjusting the rate. If a current is running and no allowance for it is made in the dead reckoning, the DR position is in error by an amount proportional to elapsed time. The error introduced by maintaining heading by means of an inaccurate compass is proportional to distance, as is the lateral error in a position line plotted from an inaccurate bearing.

One of the causes of equation of time (art. 611) is the fact that the ecliptic, around which annual motion occurs, is not parallel to the celestial equator, around or parallel to which apparent daily motion takes place. The same type systematic error is involved in other measurements. Consider the measurement of bearing with a tilted compass card. Bearing is measured by a system of uniform graduations (degrees) of a circle (such as a compass card) in the horizontal plane. If the card is tilted, and its graduations are projected onto the horizontal plane, the circle becomes an ellipse with the graduations unequally spaced. Along the axis of tilt and a line perpendicular to it, directions are correct. But near the axis of tilt the graduations are too close together, and near the perpendicular they are too widely spaced. The error thus introduced is similar to that which would arise if a watch face were tilted but the motion of the hands remained horizontal. If it were tilted around the "3–9" line, it would appear to run slow near the hour and half hour, and fast near the quarter and three-quarter hours. If the direction to be observed is of an object above or below the horizontal, as the azimuth of a celestial body, measurement is made to the foot of the perpendicular through the object. The sight vanes of a compass move in a plane perpendicular to the compass card. Hence, if the card is tilted, measurement is made to the foot of a perpendicular to the card, rather than to the foot of a perpendicular to the horizontal, introducing an error which increases with the angle of tilt and also with the angle of elevation (or depression) of the object. This error is greatest along the axis of tilt, and zero along the perpendicular to it. Both of these tilt errors can be corrected by leveling the compass card.

A different type of tilt error occurs when a reflection takes place from a tilted surface, such as the ionosphere, the error being proportional to the angle of tilt. In some respects, this error is similar to coastal refraction of a radio wave.

Additional examples of systematic error are uncorrected deviation of the compass, error due to a position in a pattern of hyperbolas, error due to incorrect location of a Loran transmitter, uncorrected parallax, and uncorrected personal error.

304. Random errors are chance errors, unpredictable in magnitude or sign. They are governed by the laws of probability. If the altitude of a celestial body is observed, the reading may be (1) too great, (2) correct, or (3) too small. If a number of observations are made, and there is no systematic error, the probability of a positive error is exactly equal to the probability of a negative error. This does not mean that every second observation having an error will be too great. However, the greater the number of observations, the greater is the probability that the number of positive errors will equal the number of negative ones, and that their magnitudes will correspond.

Error	No. of obs.	Percent of obs.
−10′	0	0. 0
− 9′	1	0. 2
− 8′	2	0. 4
− 7′	4	0. 8
− 6′	9	1. 8
− 5′	17	3. 4
− 4′	28	5. 6
− 3′	40	8. 0
− 2′	53	10. 6
− 1′	63	12. 6
0	66	13. 2
+ 1′	63	12. 6
+ 2′	53	10. 6
+ 3′	40	8. 0
+ 4′	28	5. 6
+ 5′	17	3. 4
+ 6′	9	1. 8
+ 7′	4	0. 8
+ 8′	2	0. 4
+ 9′	1	0. 2
+10′	0	0. 0
0	500	100. 0

TABLE 304.—Normal distribution of random errors.

Suppose that 500 observations are made, with the results shown in table 304. A close approximation of the plot of these errors is shown in figure 304a. The plot has been modified slightly to constitute the **normal curve** of random errors, which is the same as the actual curve except that the normal curve *approaches* zero as the error increases, while the actual curve *reaches* zero at (+)10′ and (−)10′. The height of the curve at any point represents the percentage of observations that can be expected to have the error indicated at that point. The probability of any similar observation having any given error is the proportion of the number of observations having this error to the total number of observations, or the percentage expressed as a decimal. Thus, the probability of an observation having an error of (−)3′ is $\frac{40}{500}=\frac{1}{12.5}=0.08$ (8%).

If the area under the curve represents 100 percent of the observations, half the area (the shaded portion of figure 304a) represents 50 percent of the observations. The value of the error at the limits of this shaded portion is often called the "50 percent error," or **probable error,** meaning that 50 percent of the observations can be expected to have less error, and 50 percent greater error. Similarly, the limits which contain the central 95 percent of the area denote the 95 percent error. The percentage of error is found mathematically. For a normal curve, each error is squared, the sum of the squares is divided by one less than the number of observations, and the square root of the quotient is determined. This value is called the **standard deviation** (σ, the Greek letter sigma). In the illustration, the standard deviation is the square root of $0\times(-)10^2+1\times(-)9^2+2\times(-)8^2+4\times(-)7^2+9\times(-)6^2$, etc., divided by 499 or $\sqrt{\frac{4474}{499}}=\sqrt{8.966}=2.99$ (about 3). The standard deviation is the 68 percent error. The probability of the occurrence of an error of or less than a specific magnitude may be determined by the following relationship (with the answers for the illustration given):

50% error= ⅔×σ= 2′ (approx.)
68% error=1 ×σ= 3′ (approx.)
95% error=2 ×σ= 6′ (approx.)
99% error=2⅔×σ= 8′ (approx.)
99.9% error=3⅓×σ=10′ (approx.)

Many of the errors of navigation are not of the "normal" type. In Pub. No. 229 values of altitude can be taken only to the nearest 0′.1. The error in tabular altitude might have any value from (+) 0′.05 to (−) 0′.05, and any value within these limits is as likely to occur as any other of the same precision. The same is true of a sextant that cannot be read closer than 0′.1, and of a Loran-A receiver that cannot be read closer than 1 μs. These values refer to the single errors indicated, and not to the total error that might be involved. This is a **rectangular error,** so called because of the shape of its plot, as shown in figure 304b. The 100 percent error is half the difference between readings. The 50 percent error is half this amount, the 95 percent error is 0.95 times this amount, etc.

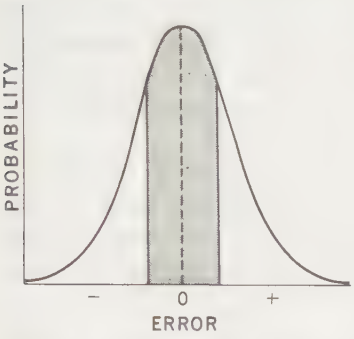

FIGURE 304a.—Normal curve of random error with 50 percent of area shaded. Limits of shaded area indicate probable error.

Still another type random error is encountered in navigation. If a compass is fluctuating periodically due to yaw of a ship, its motion slows as the end of a swing is approached, when the error approaches maximum value. If readings were taken continuously or at equal intervals of time, the interval being a small percentage of the total period of oscillation, the curve of errors would have a characteristic U-shape, as shown in figure 304c. The same type error is involved in measurement of altitude of a celestial body from a wing of the bridge of a heavily rolling vessel, when the roll causes large changes in the height of eye. This type of error is called a **periodic error.** The effect is accentuated by the tendency of the observer to make readings near one of the extreme values because the instrument appears steadiest at this time. If it is impractical to make a reading at the center of the period, the error can be eliminated or reduced by averaging readings taken continuously or at short intervals, as indicated above. This is the method used in averaging type artificial-horizon sextants. Generally, better results can be obtained by taking maximum positive and maximum negative readings, and averaging the results.

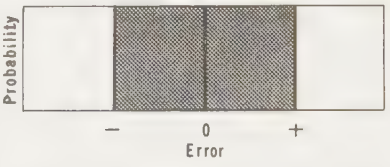

FIGURE 304b.—Rectangular error, with 50 percent area shaded.

The curve of any type of random error is symmetrical about the line representing zero error. This means that in the ideal plot every point on one side of the curve is exactly matched by one on the other side, or for every positive error there is a negative error of the same magnitude. The average of all readings, considering signs, is zero. The larger the number of readings, the greater the probability of the errors fitting the ideal curve. Another way of stating this is that as the number of readings increases, the error of the average can be expected to decrease

FIGURE 304c.—Periodic error, with 50 percent area shaded.

305. Combinations of errors.—Many of the results obtained in navigation are subject to more than one error. Chapter VIII lists 19 errors applicable to sextant altitudes. Some of these have several components. A number of possible errors are involved in the determination of computed altitude and azimuth. A rectangular error is possible in finding the altitude difference. Several additional errors may

affect the accuracy of plotting. Thus, the line of position as finally plotted may include 30 errors or more. Corrections are applied for some of the larger ones, so that in each of these cases the applicable error is the difference between the applied correction and the actual error. Thus, a dip correction may be applied for a height of eye of 30 feet, while the actual height at the moment of observation may be 31 feet 6 inches. Even if the height of eye is exactly 30 feet, a rectangular error may be involved in taking the dip correction from the table.

Corrections which might be random as far as an individual observation is concerned may be systematic for a series of observations. Thus, if the average or standard conditions upon which a correction is based do not exist at the time of observation the value at any given time is as likely to be greater as it is to be less than the standard amount. But if a number of observations are taken in quick succession, the error will be about the same for each.

If two or more errors are applicable to a given result, the total error is equal to the algebraic sum of all errors. Thus, if a given number is subject to errors of (+) 4, (−) 2, (−) 1, (+) 3, (+) 2, 0, and (−) 2, the total error is (+) 4. Systematic errors can be combined by adding the curves of individual errors. Thus, a magnetic compass may have a quadrantal error as shown by the top curve of figure 305, and a semicircular error as shown by the second curve. The sum of these two errors is shown in the bottom curve. If, in addition, the compass has a constant error, the bottom curve is moved vertically upward or downward by the amount of the constant error, without undergoing a change of form. If the constant error is greater than the maximum value of the combined curves, all errors are positive or all are negative, but of varying magnitude.

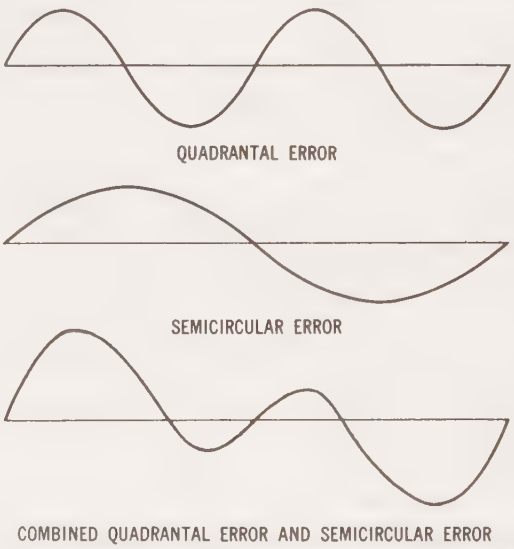

FIGURE 305.—Combining systematic errors.

If a number of random errors are combined, the result tends to follow a normal curve regardless of the shape of the individual errors, and the greater the number, the more nearly the result can be expected to approach the normal curve (fig. 304a). If a given result is subject to errors of plus or minus 3, 2, 1, 2, 4, 2, 1, 8, 1, and 2, the total error *could* be as much as 26 if all errors had the same sign. However, if these are truly random, the probability of them all having the same sign is only one in 1024. This is so because the chance of any one being positive (or negative) is ½. That is, of a large number of results, approximately half will have any one particular correction positive (or negative). By the same reasoning, approximately half of the positive (or negative) results will have any one particular additional correction positive (or negative). Thus, the probability of any two particular corrections having a positive (or negative) sign is $\frac{1}{2}\times\frac{1}{2}=(\frac{1}{2})^2=\frac{1}{4}$. The probability of all ten corrections having a positive (or negative) sign is $(\frac{1}{2})^{10}=\frac{1}{1024}$. If there were 20 corrections, the probability of all having a positive (or negative) sign would be $(\frac{1}{2})^{20}=\frac{1}{1,048,576}$.

The standard deviation of the *sum* of such errors is found by squaring each error individually, *adding* the results and taking the square root of the sum. Thus, in the example, the following results are obtained:

Error	*Error Squared*
3	9
2	4
1	1
2	4
4	16
2	4
1	1
8	64
1	1
2	4
sum	108
square root	±10.4

Thus, the standard deviation is ±10.4. Signs need not be considered because the square of either a positive or negative number is positive.

The individual errors have been treated as if they were fixed in amount. If they are 50 percent normal errors, the result is the standard deviations of the 50 percent errors; if 99 percent, the result is the standard deviations of the 99 percent errors, etc., *if* the individual errors are normal and independent. If they are of a different type, an adjustment is needed. Thus, the square of each rectangular error should be multiplied by the following factors:

50% error ⅔
95% error 1⅔
99% error 2½
99.9% error 4.

The information required to determine the standard deviation is usually not available to a navigator, because the probable magnitude of many of the individual errors has never been determined. However, the example given above reveals at least one interesting point which is highly practical. In the tabulation of errors, the largest has a value of eight. This single error accounts for less than one-third the total *possible* error, but its square is more than half the sum of squares. If this error could be eliminated, the standard deviation would be only 6.6. If it could be reduced to 5, a 37.5 percent reduction, the standard deviation would be reduced to 8.3. In contrast, if the next largest error, four, were reduced by three, a reduction of 75 percent, the standard deviation would be reduced by only 0.8, to 9.6. If the three errors of one each could be completely eliminated, the standard deviation would be reduced by only 0.2, to 10.2. In the reduction of total error, therefore, a relatively small reduction in a large error has a much greater effect upon the standard deviation than the same numerical reduction (larger percentage reduction) in a small error, because the result of a random error is proportional to its square.

Therefore, the perfection of one part of a process, sometimes at great expense or by the introduction of considerable inconvenience, may not be justified until larger

errors are corrected. Thus, it would hardly be worth the effort and expense to build a Loran-A receiver capable of making a reading to 0.1 μs (present receivers can be read to about 1 μs) as long as synchronization of signals may be in error as much as 2 μs or more. Conversely, the introduction of an additional small error may add considerably to the convenience of a process without materially affecting the accuracy. Thus, the use of some of the "short" methods of sight reduction without interpolation is justified if the interval of tabulation is small.

When both systematic and random errors are present in a process, both effects are present. An increase in the number of readings decreases the residual random error, but regardless of the number of readings, a systematic error is present in its entirety. Thus, if a number of Decca readings are made at a fixed point, the average should be a good approximation of the true value if there is no systematic error. But if the equipment is out of adjustment to the extent that the lane is incorrectly identified, no number of readings will correct this error. In this illustration, a constant error is combined with a normal random error. The normal curve has the correct shape, but is offset from the zero value.

Under some conditions, systematic errors can be eliminated from the results even when the magnitude is not determined. Thus, if two celestial bodies differ in azimuth by 180°, and the altitude of each is observed, the line midway between the lines of position resulting from these observations is free from any *constant* error in the *altitude* (such as abnormal refraction or dip, or incorrect IC). It would *not* be free from such a constant error as one in time (unless the bodies were on the celestial meridian). Similarly, a fix obtained by observations of three stars differing in azimuth by 120°, or four stars differing by 90° is free from constant error in the altitude, if the center of the figure made by the lines of position is used. The center of the figure formed by circles of position from distances of objects equally spaced in azimuth is free from a constant error in range. A constant error in bearing lines does not introduce an error in the fix if the objects are equally spaced in azimuth. In all of these examples, the correct position is *outside* the figure formed by the lines of position if all objects observed are on the same side of the observer (that is, if they lie within an arc of less than 180°).

306. Most probable position.—Some navigators, particularly those of little experience, have been led by the simplified definitions and explanations usually given in texts to conclude that the line of position is infallible, and that a fix is without error, overlooking the frequent incompatibility of these two notions. Too often the idea has prevailed that information is either all right or all wrong. An example is the practice of establishing an estimated position at the foot of the perpendicular from a dead reckoning position to a line of position. The assumption is that the vessel *must* be somewhere on the line of position. The limitations of this often valuable practice are not understood by these inexperienced navigators.

A more realistic concept is that of the **most probable position (MPP),** which recognizes the probability of error in *all* navigational information, and determines position by an evaluation of all available information, using the principles of errors.

Suppose a vessel were to start from a completely accurate position and proceed on dead reckoning. If course and speed over the bottom were of equal accuracy, the uncertainty of dead reckoning positions would increase equally in all directions with either distance or elapsed time (for any one speed these would be directly proportional and therefore either could be used). Therefore, a circle of uncertainty would grow around the dead reckoning position as the vessel proceeded. If the navigator had full knowledge of the distribution and nature of the errors of course and speed, and the necessary knowledge of statistical analysis, he could compute the radius of the circle of uncertainty, using the 50 percent, 95 percent, or other value of individual errors.

In ordinary navigation, this is not practicable, but based upon his experience and judgment, the navigator might estimate at any time the probable error of his dead reckoning or estimated position. With practice, he might acquire considerable skill in making this estimate. He would take into account, too, the fact that the area of uncertainty might better be represented by an ellipse than a circle, the major axis being along the course line if the probable error of the speed were greater than that of the course, and the minor axis being along the course line if the probable error of the course were greater. He would recognize, too, that the size of the area of uncertainty would not grow in direct proportion to the distance or elapsed time, because disturbing factors such as wind and current could not be expected to remain of constant magnitude and direction. Also, he would know that the starting point of the dead reckoning would not be completely free from error.

At some future time additional positional information would be obtained. This might be a line of position from a celestial observation or by Omega. This, too, would be accompanied by a probable error which might be computed if the necessary information and knowledge were available, but which in practice would be estimated. If the dead reckoning had started from a good position obtained by means of landmarks, the probable error of the initial position would be very small. At first the dead reckoning or estimated position would probably be more reliable than a line of position obtained by celestial observation or Omega. But at *some* distance the two would be equal, and beyond this the line of position might be more accurate.

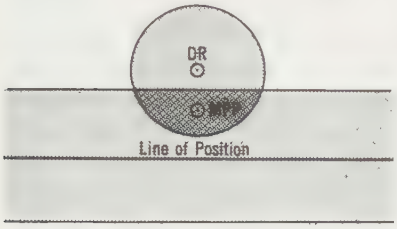

FIGURE 306a.—A most probable position based upon a dead reckoning position and line of position having equal probable errors.

However, the determination of most probable position does not depend upon determination of *which* information is most accurate. In figure 306a a dead reckoning position is shown surrounded by a circle of uncertainty. A line of position is also shown, with its area of uncertainty. The most probable position is within the overlapping area, and if the uncertainty of the dead reckoning position and that of the line of position are about equal, it might be taken at the center of the area. If the overall errors are considered normal, and they are probably approximately so, *the effect of each error is proportional to its square*. Thus, if the probable error of a dead reckoning position is three miles, and that of a line of position is two miles, the most probable position is nearer the line of position, being at a distance equal to $\frac{2^2}{3^2}=\frac{4}{9}$ that from the dead reckoning position (or $\frac{4}{13}$ of the perpendicular distance from the dead reckoning position to the line of position).

If a fix is obtained from two lines of position, the area of uncertainty is a circle if the lines are perpendicular, have equal probable errors, and these errors can be considered normal. If one is considered more accurate than the other, the area is an ellipse, the two axes being proportional to the standard deviations of the two LOP's. As shown in figure 306b, it is also an ellipse if the probable error of each

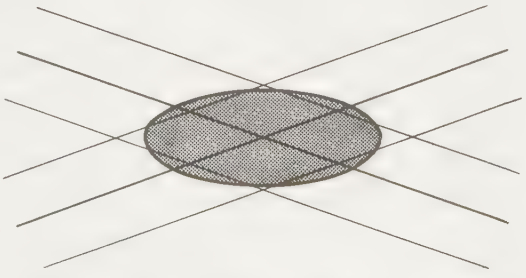

FIGURE 306b.—Ellipse of uncertainty with lines of position of equal probable errors crossing at an oblique angle.

is equal and the lines cross at an oblique angle. If the errors are unequal, the major axis of the ellipse is more nearly in line with the line of position having the smaller probable error. If the angle between lines is very small, they are better considered a single line of position in the direction of the major axis of the ellipse.

If a fix is obtained from three or more lines of position, and the error of each line is normal and equal to that of the others, the most probable position is the center of the figure. By "center" is meant that point within the figure which is equidistant from the sides. If the lines are of unequal probable error, the distance of the most probable position from each line of position is proportional to the *square* of the probable error of that line times the sine of the angle formed by the other two lines.

In the discussion of most probable position from lines of position, it has been assumed that no other positional information is available. Usually, this is an incorrect assumption, for there is nearly always a dead reckoning or estimated position. This can be considered in any of several ways. The square of its probable error can be used in the same manner as the square of the probable error of each line of position. A most probable position based upon the dead reckoning or estimated position and the most reliable line of position might be determined as explained above, and that line of position replaced with a new one parallel to it but passing through the most probable position just determined. This adjusted line of position can then be assigned a smaller probable error and used with the other lines of position to determine the overall most probable position. A third way is to establish a probable error for the fix, and consider the most probable position as that point along the straight line joining the fix and the dead reckoning or estimated position, the relative distances being equal to the square of the probable error of each position.

The value of the most probable position determined as suggested above depends upon the degree to which the various errors are in fact normal, and the accuracy with which the probable error of each is established. From a practical standpoint, the second factor is largely a matter of judgment based upon experience. It might seem that interpretation of results and establishment of most probable position is a matter of judgment anyway, and that the procedure outlined above is not needed. If a person will follow this procedure while gaining experience, and evaluate his results, the judgment he develops should be more reliable than if developed without benefit of a knowledge of the principles involved. The important point to remember is that the relative effects of normal random errors in any one direction are proportional to their *squares*.

Systematic errors are treated differently. Generally, an attempt is made to discover the errors and eliminate them or compensate for them. In the case of a position determined by three or more lines of position resulting from readings with constant error, the error might be eliminated by finding and applying that correction (including sign) which will bring all lines through a common point.

307. Mistakes.—The recognition of a mistake, as contrasted with an error (art. 302), is not always easy, since a mistake may have any magnitude, and may be either positive or negative. A large mistake should be readily apparent if the navigator is alert and has an understanding of the size of error to be reasonably expected. A small mistake is usually not detected unless the work is checked.

If results by two methods are compared, as a dead reckoning position and a line of position, exact agreement is not to be expected. But if the discrepancy is unreasonably large, a mistake is logically suspected. The definition of "unreasonably large" is a matter of opinion. If the 99.9 percent areas of the two results just touch, it is *possible*

that no mistake has been made. However, the *probability* of either one having so great an error is remote if the errors are normal. The probability of both having 99.9 percent error of opposite sign at the same instant is very small indeed. Perhaps a reasonable standard is that unless the most accurate result lies within the 95 percent area of the least accurate result, the possibility of a mistake should be investigated. Thus, if the areas of uncertainty shown in figure 306a represent the 95 percent areas, it is probable that a mistake has been made.

As in other matters pertaining to navigation, judgment is important. The use to be made of the results is certainly a consideration. In the middle of an ocean passage a mistake is usually not serious, and will undoubtedly be corrected before it jeopardizes the safety of the vessel. But if landfall is soon to be made, or if search and rescue operations are to be based upon the position, almost any mistake is intolerable.

308. Navigation accuracy is normally expressed in terms of the error between the point desired and the point achieved during the navigation process. In general, the error is statistical in character and can only be expressed in terms of a distance unlikely to be exceeded in some percentage of cases.

If the errors follow a normal distribution (art. 304), the specified distance may be stated as the standard deviation or some multiple thereof. The distance as stated for the standard deviation is measured from the arithmetic mean of the positions which could be established from a large number of observations at a given place and time. Therefore, this distance does not indicate the separation between the fix position and the observer's actual position, except by chance. If the error is stated as 1σ, 68 percent of the cases should result in position displacements from the arithmetic mean in any direction not exceeding the distance specified for 1σ. If the error is stated as 2σ, 95 percent of the positions should not be displaced from the arithmetic mean in any direction by more than the distance specified for 2σ. If the error is stated as the **probable error,** 50 percent of the positions should not be displaced from the arithmetic mean in any direction by more than the distance specified for $2/3\sigma$.

Sometimes the term **root mean square** (**RMS**) is used with the same meaning as standard deviation. However, the standard deviation and root mean square of a set of measured errors are identical only for a normal distribution where zero error is the center of the distribution or where no constant error (**bias**) exists.

In a navigation system, **predictability** is the measure of the accuracy with which the system can define the position in terms of geographical coordinates; **repeatability** is the measure of the accuracy with which the system permits the user to return to a position as defined only in terms of the coordinates peculiar to that system. **Predictable accuracy,** therefore, is the accuracy of positioning with respect to geographical coordinates; **repeatable accuracy** is the accuracy with which the user can return to a position whose coordinates have been measured previously with the same system. For example, the distance specified for the repeatable accuracy of a system such as Loran-A is the distance between two Loran-A positions established using the same stations and time-difference readings at different times.

Relative accuracy is the accuracy with which a user can determine his position relative to that of the user of the same navigation system at the same time. Hence, a system with high relative accuracy provides good rendezvous capability for the users of the system.

309. Miscellaneous.—The correct identification of the nature of an error is important if the error is to be handled intelligently. Thus, the statement is sometimes made that a radio bearing need not be corrected if the receiver is within 50 miles of the transmitter. The need for a correction arises from the fact that radio waves are assumed to

follow great circles, and if radio bearings are to be plotted on a Mercator chart, the equivalent rhumb line is needed. The statement regarding 50 miles implies that the size of the correction is proportional to distance only. It overlooks the fact that latitude and direction of the bearing line are also important factors, and is therefore a dangerous statement unless its limitations are understood.

The recognition of the type of error is also important. A systematic error has quite a different effect than a random error, and cannot be reduced by additional readings unless some method or procedure is instituted which will cause the errors to cancel each other. If a position is subject to a rectangular error only, its 100 percent error parallelogram has four times the area of the 50 percent error parallelogram. But if the error is normal, the 95 percent ellipse has approximately three times the axis and *nine* times the area of the 50 percent ellipse. It is not correct to suppose that a craft is as likely to be at one point within an ellipse of uncertainty as at any other point. If the error is normal, the probability might be represented by a three-dimensional figure formed by rotating the normal curve (fig. 304a) around its axis of symmetry, elongated along the major axis.

The probable error is usually of greater interest than the "average" value. The average of a large number of normal errors approaches zero, but the probable error might be quite large. An average or mean value determined by a number of observations is sometimes given with its probable error. Thus, a person might make a number of measurements of the speed of light and state his results as $299{,}792 \pm 2$ kilometers per second.

A person who understands the nature of errors avoids many pitfalls, Thus, the magnitude of the errors of individual lines of position is not a reliable indication of the size of the error of the fix obtained from them. The size of the triangle formed by three lines of position has often been used as a guide to the accuracy of the fix, although a large triangle might be the result of a large constant error if the objects observed are equally spaced in azimuth. On the other hand, two lines of position with small errors might produce a fix having a much larger error if the lines cross at a small angle.

The size of a triangle of position might be deceptive for another reason. A constant error in time shifts all lines of position from celestial observation an approximately equal amount (in minutes of arc) toward the east or toward the west. If all objects observed for a fix are on the same side of the observer, a constant error in measurement shifts all objects *and the fix,* so that if the constant error is larger than the random error, the actual position is outside the figure formed by the lines of position.

CHAPTER IV

MEASUREMENT ON THE EARTH

401. The earth is approximately an **oblate spheroid** (a sphere flattened at the poles). Approximations of its dimensions and the amount of flattening are given in appendix D. However, for many navigational purposes, the earth is assumed to be a sphere, without intolerable error.

The **axis of rotation** or **polar axis** of the earth is the line connecting the north pole and the south pole.

402. Circles of the earth.—A **great circle** is the line of intersection of a sphere and a plane through the center of the sphere. This is the largest circle that can be drawn on a sphere. The shortest line on the surface of a sphere between two points on that surface is part of a great circle. On the spheroidal earth the shortest line is called a **geodesic.** A great circle is a near enough approximation of a geodesic for most problems of navigation.

A **small circle** is the line of intersection of a sphere and a plane which does not pass through the center of the sphere.

A **meridian** is a great circle through the geographical poles of the earth. Hence, all meridians meet at the poles, and their planes intersect each other in a line, the **polar axis** (fig. 402a). The term **meridian** is usually applied to the **upper branch** only, that half from pole to pole which passes through a given point. The other half is called the **lower branch.**

The **prime meridian** is that meridian used as the origin for measurement of longitude (fig. 402b). The prime meridian used almost universally is that through the original position of the British Royal Observatory at Greenwich, near London.

The **equator** is the terrestrial great circle whose plane is perpendicular to the polar axis (fig. 402c). It is midway between the poles.

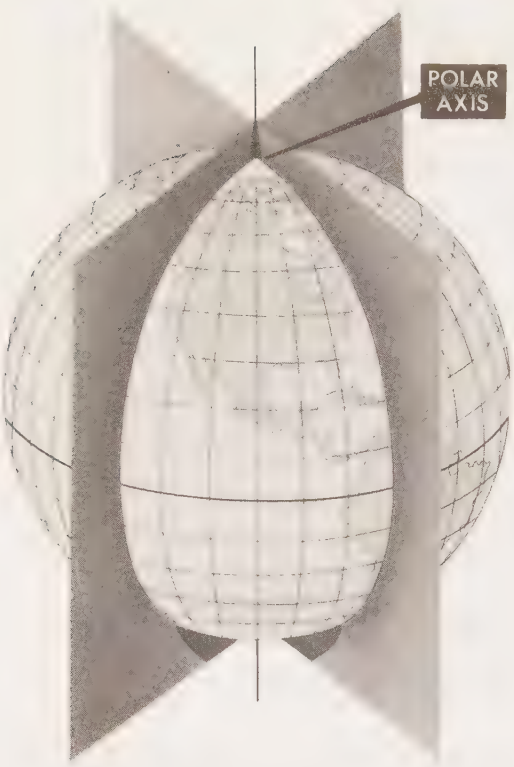

FIGURE 402a.—The planes of the meridians meet at the polar axis.

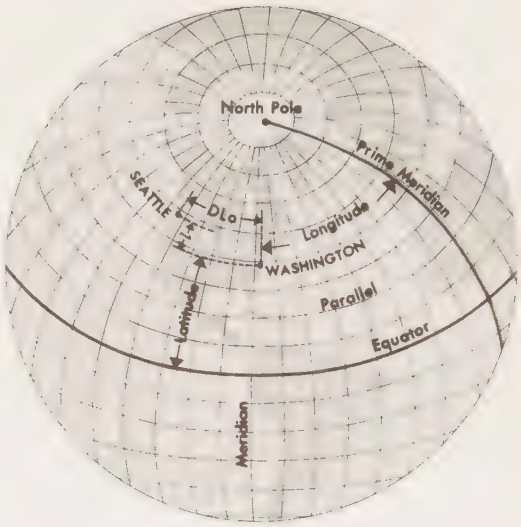

FIGURE 402b.—Circles and coordinates of the earth. All parallels except the equator are small circles; the equator and meridians are great circles.

A **parallel** or **parallel of latitude** is a circle on the surface of the earth, parallel to the plane of the equator (fig. 402d). It connects all points of equal latitude. The equator, a great circle, is a limiting case connecting points of 0° latitude. The poles, single points at latitude 90°, are the other limiting case. All other parallels are small circles.

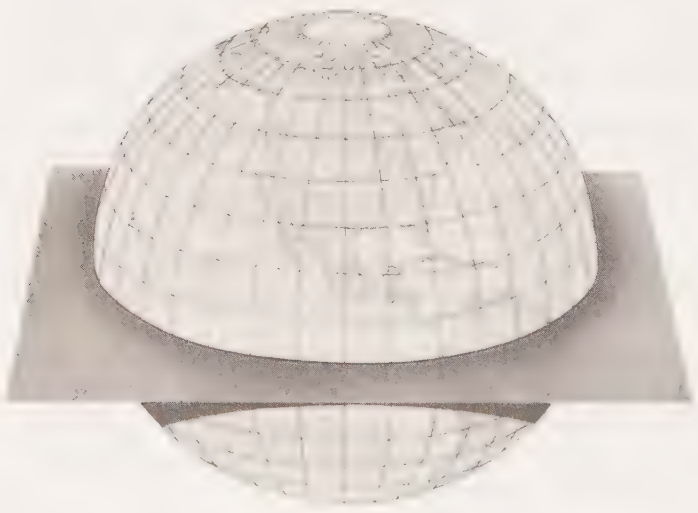

FIGURE 402c.—The equator is a great circle midway between the poles.

403. Position on the earth.—A position on the surface of the earth (except at either of the poles) may be defined by two magnitudes called **coordinates.** Those customarily used are *latitude* and *longitude.* A position may also be expressed in relation to known geographical positions.

Latitude (**L, lat.**) is angular distance from the equator, measured northward or southward along a meridian from 0° at the equator to 90° at the poles (fig. 402b). It is designated *north* (N) or *south* (S) to indicate the direction of measurement.

The **difference of latitude** (*l*, **D. Lat.**) between two places is the angular length of arc of any meridian between their parallels (fig. 402b). It is the numerical difference of the latitudes if the places are on the same side of the equator, and the sum if they are on opposite sides. It may be designated *north* (N) or *south* (S) when appropriate.

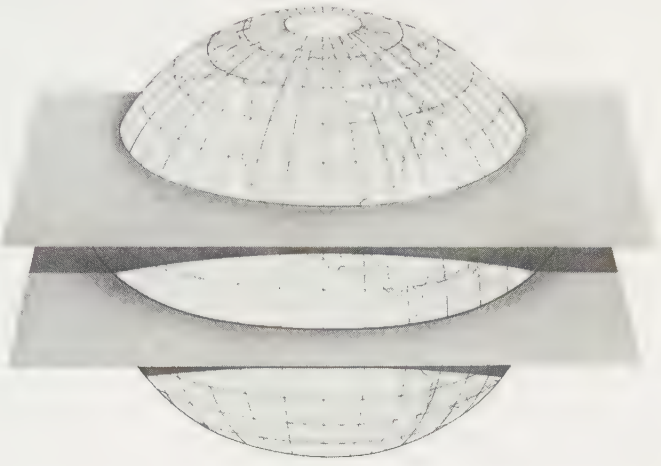

FIGURE 402d.—A parallel of latitude is parallel to the equator.

The **middle** or **mid latitude** (**Lm**) between two places on the same side of the equator is half the sum of their latitudes. Mid latitude is labeled N or S to indicate whether it is north or south of the equator. The expression is occasionally used with reference to two places on opposite sides of the equator, when it is equal to half the *difference* between the two latitudes, and takes the name of the place farthest from the equator. However, this usage is misleading, as it lacks the significance usually associated with the expression. When the places are on opposite sides of the equator, two mid latitudes are generally used, the average of each latitude and 0°.

Longitude (λ, **long.**) is the arc of a parallel or the angle at the pole between the prime meridian and the meridian of a point on the earth, measured eastward or westward from the prime meridian through 180° (fig. 402b). It is designated *east* (E) or *west* (W) to indicate the direction of measurement.

The **difference of longitude** (**DLo**) between two places is the shorter arc of the parallel or the smaller angle at the pole between the meridians of the two places (fig. 402b). If both places are on the same side (east or west) of Greenwich, DLo is the numerical difference of the longitudes of the two places; if on opposite sides, DLo is the numerical sum unless this exceeds 180°, when it is 360° minus the sum. The distance between two meridians at any parallel of latitude, expressed in distance units, usually nautical miles, is called **departure** (**p, Dep.**). It represents distance made good to the east or west as a craft proceeds from one point to another. Its numerical value between any two meridians decreases with increased latitude, while DLo is numerically the same at any latitude. Either DLo or p may be designated *east* (E) or *west* (W) when appropriate.

404. Distance on the earth.—Distance (**D, Dist.**) is the spatial separation of two points, and is expressed as the length of a line joining them. On the surface of the

earth it is usually stated in miles. Navigators customarily use the **nautical mile** (**mi., M**) of 1852 meters exactly. This is the value suggested by the International Hydrographic Bureau in 1929, and since adopted by most maritime nations. It is often called the **International Nautical Mile** to distinguish it from slightly different values used by some countries. On July 1, 1959, the United States adopted the exact relationship of 1 yard=0.9144 meter. The length of the International Nautical Mile is consequently equal to 6,076.11549 feet (approximately).

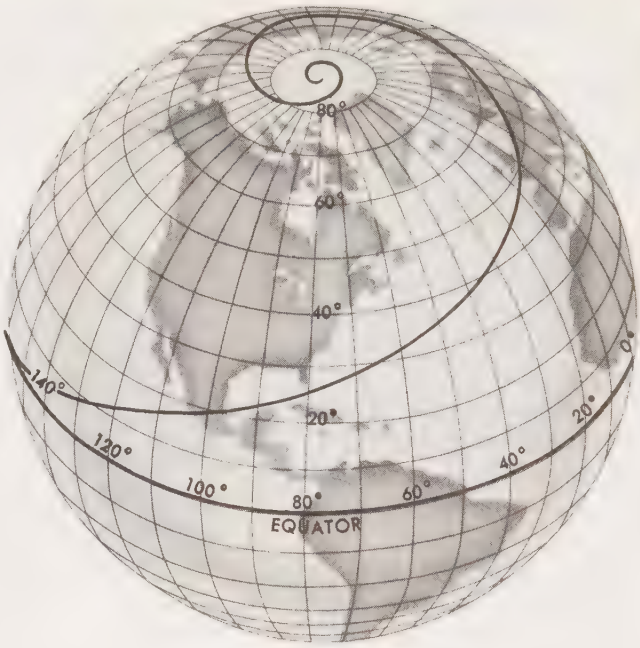

FIGURE 404.—A rhumb line or loxodrome.

For most navigational purposes the nautical mile is considered the length of one minute of latitude, or of any great circle of the earth, regardless of location. On the Clarke spheroid of 1866, used for mapping North America, the length of one minute of latitude varies from about 6,046 feet at the equator to approximately 6,108 feet at the poles. The length of one minute of a great circle of a sphere having an area equal to that of the earth, as represented by this spheroid, is 6,080.2 United States feet. This was the standard value of the nautical mile in the United States prior to adoption of the international value. A **geographical mile** is the length of one minute of the equator, or about 6,087 feet.

The **land** or **statute mile** (**mi., St M**) of 5,280 feet is commonly used for navigation on rivers and lakes, notably the Great Lakes of North America.

The nautical mile is about 38/33 or approximately 1.15 statute miles. A conversion table for nautical and statute miles is given in table 20.

Distance, as customarily used by the navigator, refers to the length of the **rhumb line** connecting two places. This is a line making the same oblique angle with all meridians. Meridians and parallels (including the equator) which also maintain constant true directions, may be considered special cases of the rhumb line. Any other rhumb line spirals toward the pole, forming a **loxodromic curve** or **loxodrome** (fig. 404). Distance along the great circle connecting two points is customarily designated **great-circle distance.**

405. Speed (**S**) is rate of motion, or distance per unit of time.

A **knot** (**kn.**), the unit of speed commonly used in navigation, is a rate of one nautical mile per hour. The expression "knots per hour" refers to acceleration, not speed.

Sometimes the expression **speed of advance** (**SOA**) is used to indicate the speed intended to be made along the track (art. 406), and **speed over ground** (**SOG**) the speed along the actual track. **Speed made good** (**SMG**) is the speed along the course made good.

406. Direction on the earth.—Direction is the position of one point relative to another, without reference to the distance between them. In navigation, direction is customarily expressed as the angular difference in degrees from a reference direction,

usually north or the ship's head. Compass directions (east, south by west, etc.) or points (of 11¼° or 1/32 of a circle) are seldom used by modern navigators for precise directions.

Course (**C, Cn**) is the intended horizontal direction of travel, expressed as angular distance from north, usually from 000° at north, clockwise through 360°. Strictly, the term applies to direction *through the water*, not the direction intended to be made good *over the ground*. The course is often designated as **true, magnetic, compass,** or **grid** as the reference direction is true, magnetic, compass, or grid north, respectively. **Course made good** (**CMG**) is the single course from the point of departure to point of arrival at any given time. Sometimes the expression **course of advance** (**COA**) is used to indicate the direction intended to be made good over the ground, and **course over ground** (**COG**) the direction of the actual track. **Course line** is a line extending in the direction of a course.

In making computations it is sometimes convenient to express a course as an angle from *either* north or south, through 90° or 180°. In this case it is designated **course angle** (**C**) and should be properly labeled to indicate the origin (prefix) and direction of measurement (suffix). Thus, C N35°E=Cn 035° (000°+35°), C N155°W =Cn 205° (360°−155°), C S47°E=Cn 133° (180°−47°). But Cn 260° may be either C N100°W or C S80°W, depending upon the conditions of the problem.

The symbol C is always used for *course angle*, and is usually used for *course* where there is little or no possibility of confusion.

Track (**TR**) is the path actually followed by a vessel, or the path of intended travel. Sometimes the term **intended track line** is used to indicate the path of intended travel (fig. 406a). The path actually followed is usually a somewhat irregular line. The path of proposed travel consists of one or a series of course lines from the point of departure to the destination, along which it is intended the vessel will proceed. A great circle which a vessel intends to follow approximately is called a **great-circle track.**

Heading (**Hdg., SH**) is the direction in which a vessel is pointed, expressed as angular distance from north, usually from 000° at north, clockwise through 360°. *Heading* should not be confused with *course*. *Heading* is a constantly changing value as a vessel oscillates or yaws back and forth across the course or as the direction of motion is temporarily changed, as in avoiding an obstacle. *Course* is a predetermined value and usually remains constant for a considerable time.

Bearing (**B, Brg.**) is the direction of one terrestrial point from another, expressed as angular distance from a reference direction, usually from 000° at the reference direction, clockwise through 360°. When measured through 90° or 180° from *either* north or south, it is called **bearing angle** (**B**), which bears the same relationship to bearing as *course angle* does to *course*. *Bearing* and *azimuth* are sometimes used interchangeably, but the latter is better reserved exclusively for reference to horizontal direction of a point on the celestial sphere from a point on the earth.

A **relative bearing** is one relative to the heading, or to the vessel itself. It is usually measured from 000° at the heading, clockwise through 360°. However, it is sometimes conveniently measured right or left from 0° at the ship's head through 180°. This is particularly true when using table 7. Older methods, such as indicating the number of degrees or points from some part of the vessel (10° forward of the starboard beam, two points on the port quarter, etc.) are seldom used by modern navigators to indicate precise directions, except for bearings dead ahead or astern, or broad on the bow, beam, or quarter.

To convert a relative bearing to a bearing from north (fig. 406b), express the relative bearing in terms of the 0°–360° system and add the heading:

$$\text{True Bearing} = \text{Relative Bearing} + \text{Heading}.$$

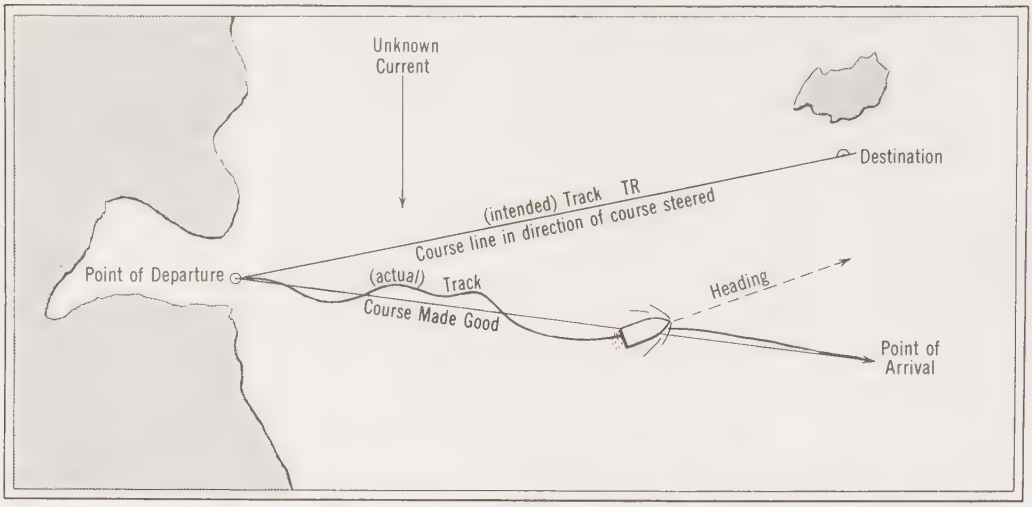

FIGURE 406a.—Course line, track, intended track, course made good, and heading.

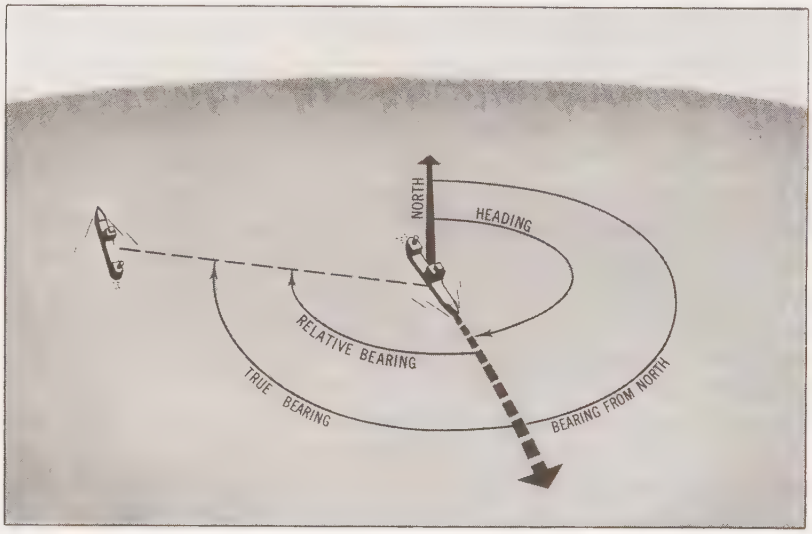

FIGURE 406b.—Relative bearing.

Thus, if another vessel bears 127° relative from a ship whose heading is 150°, the bearing from north is 127°+150°=277°. If the total exceeds 360°, subtract this amount. To convert a bearing from north to a relative bearing, subtract the heading:

$$\text{Relative Bearing} = \text{True Bearing} - \text{Heading}$$

Thus, a lightship which bears 241° from north bears 241°−137°=104° relative from a ship whose heading is 137°. If the heading is larger than the true bearing, add 360° to the true bearing before subtracting.

407. Grid direction.—Because of the rapid convergence of the meridians in polar regions, the true direction of an oblique line near the pole may vary considerably over a relatively few miles. The meridians are radial lines meeting at the poles, instead of being parallel, as they appear on the familiar Mercator chart.

Near the pole the convenience of parallel meridians is attained by means of a **polar grid.** On the chart a number of lines are printed parallel to a selected reference

meridian, usually that of Greenwich. On transverse Mercator charts the fictitious meridians may serve this purpose. Any straight line on the chart makes the same angle with all grid lines. On the transverse Mercator projection it is therefore a **fictitious rhumb line.** On any polar projection it is a close approximation to a great circle. If north along the reference meridian is selected as the reference direction, all parallel grid lines can be considered extending in the same direction. The constant direction relative to the grid lines is called **grid direction.** North along the Greenwich meridian is usually taken as grid north in both the northern and southern hemispheres.

The value of grid directions is indicated in figure 407. In this figure A and B are 400 miles apart. The true bearing of B from A is 023°, yet at B this bearing line, if continued, extends in true direction 163°, a change of 140° in 400 miles. The grid direction at any point along the bearing line is 103°.

When north along the Greenwich meridian is used as grid north, interconversion between grid and true directions is quite simple. Let G represent a grid direction and T the corresponding true direction. Then for the arctic,

$$G=T+\lambda W.$$

That is, in the western hemisphere, in the arctic, grid direction is found by *adding* the longitude to the true direction. From this it follows that

$$T=G-\lambda W,$$

and in the eastern hemisphere

$$G=T-\lambda E,$$
$$T=G+\lambda E.$$

In the southern hemisphere the signs (+ or −) of the longitude are reversed in all formulas.

If a magnetic compass is used to follow a grid direction, variation and convergency can be combined into a single correction called **grid variation** or **grivation.** It is customary to show lines of equal grivation (**isogrivs**) on polar charts rather than lines of equal variation.

With one modification the grid system of direction can be used in any latitude. Meridians 1° apart make an angle of 1° with each other where they meet at the pole. The **convergency** is one, and the 360° of longitude cover all 360° around the pole. At the equator the meridians are parallel and the convergency is zero. Between these two limits the convergency has some value between zero and one. On a sphere it is equal to the sine of the latitude. For practical navigation this relationship can be used on the spheroidal earth. On a simple conic or Lambert conformal chart a constant convergency is used over the entire chart, and is known as the **constant of the cone.** On a simple conic projection it is equal to the sine of the standard parallel. On a Lambert conformal projection it is equal (approximately) to the sine of the latitude midway between the two standard parallels. When convergency is printed on the chart, it is generally adjusted for ellipticity of the earth. If K is the constant of the cone,

$$K=\sin \tfrac{1}{2} (L_1+L_2) \text{ approx.},$$

where L_1 and L_2 are the latitudes of the two standard parallels. On such a chart, grid navigation is conducted as explained above, except that in each of the formulas the longitude is multiplied by K:

$$G=T+K\ \lambda W,$$
$$T=G-K\ \lambda W,$$
$$G=T-K\ \lambda E,$$
$$T=G+K\ \lambda E.$$

Thus, a straight line on such a chart changes its true direction, not by 1° for each degree of longitude, but by $K°$. As in higher latitudes, convergency and variation can be combined.

In using grid navigation one should keep clearly in mind the fact that the grid lines are parallel *on the chart*. Only on the transverse Mercator and polar gnomonic projections do the grid lines have geographical significance. On these projections, the grid lines are great circles which meet at "poles" on the equator, 90° from the meridian used as the fictitious equator. Since distortion varies on charts of different projections, and on charts of conic projections having different standard parallels, *the grid direction*

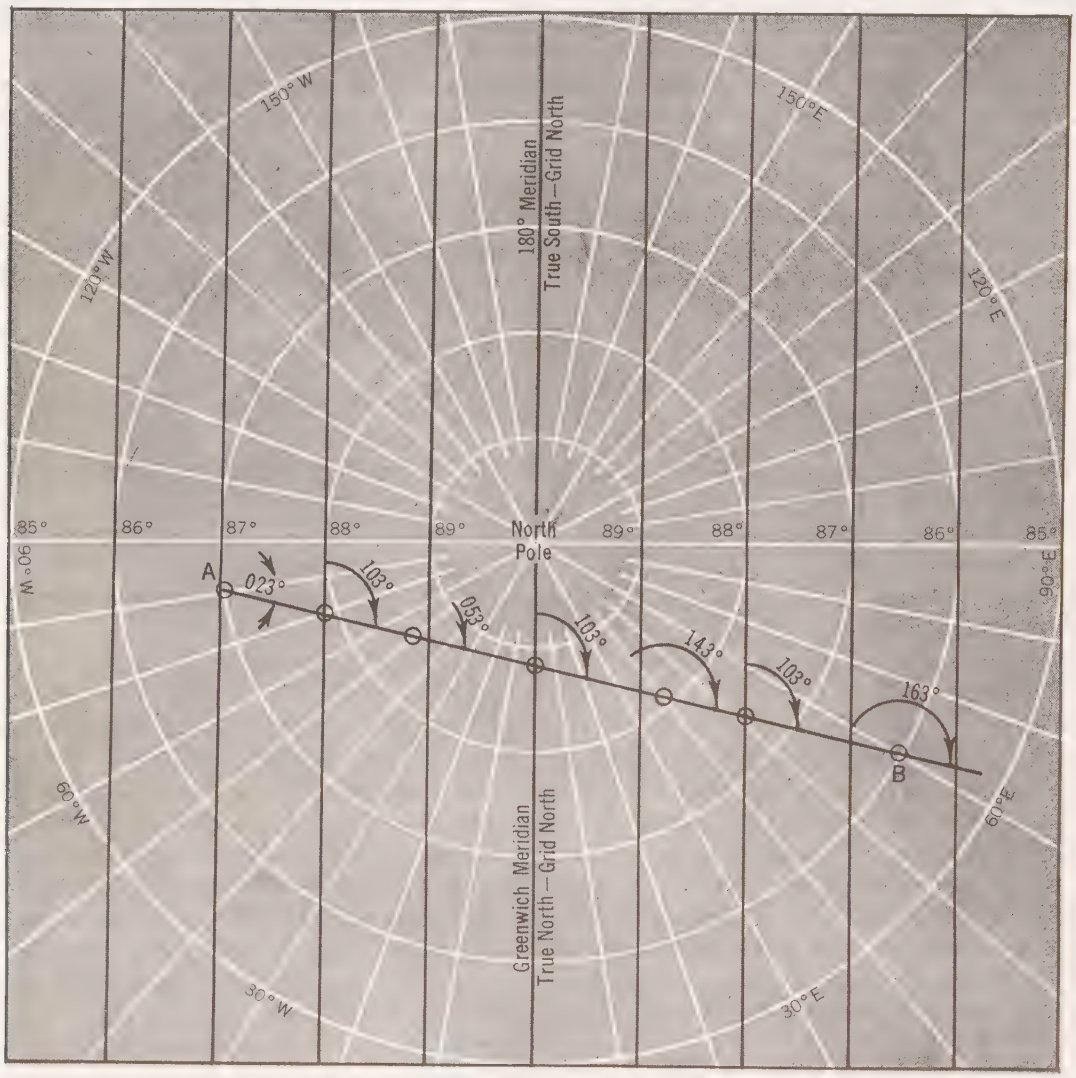

FIGURE 407.—Polar grid navigation.

between any two given points is not the same on all charts. For operations which are to be coordinated by means of grid directions, *it is important that all charts showing the grid be on a single graticule.*

Problems

403. *Given.*—Point A: L 37°21′.4N, λ 143°18′.8W; Point B: L 43°04′.1N, λ 11°47′.3E; Point C: L 63°24′.4S, λ 132°06′.9E; Point D: L 2°36′.6S, λ 168°01′.2W.

Required.—(1) The difference of latitude between A and B, between A and C, and between C and D.

(2) The difference of longitude between A and B, A and C, and B and C.

Answers.—(1) l_{AB} 5°42′.7N, l_{AC} 100°45′.8S, l_{CD} 60°47′.8N; (2) DLo_{AB} 155°06′.1E, DLo_{AC} 84°34′.3W, DLo_{BC} 120°19′.6E.

404a. The distance between points E and F is 258.4 nautical miles.

Required.—The distance in statute miles between points E and F (1) by proportion, using the ratio given in article 404; (2) by conversion factor, using the value given in article 404; (3) by table 20.

Answers.—(1) D 297.6 St M, (2) 297.2 St M, (3) D 297.4 St M.

404b. The distance between points G and H is 83.3 statute miles.

Required.—The distance in nautical miles between points G and H (1) by proportion, using the ratio given in article 404; (2) by conversion factor, using the value given in article 404; (3) by table 20.

Answers.—(1) D 72.3 M, (2) D 72.4 M, (3) D 72.4 M.

405a. A ship is steaming at 18.5 knots.

Required.—The speed in statute miles per hour.

Answer.—S 21.3 mph.

405b. A motorboat is traveling at 30 statute miles per hour.

Required.—The speed in knots.

Answer.—S 26 kn.

406a. *Required.*—Convert the following course angles to courses: (1) N 127°W, (2) S3°W, (3) N99°E, (4) S171°E.

Answers.—(1) Cn 233°, (2) Cn 183°, (3) Cn 099°, (4) Cn 009°.

406b. *Required.*—Convert the following courses to course angles, giving the two possible answers of each: (1) 153°, (2) 257°.

Answers.—(1) C N153°E or S27°E, (2) C N103°W or S77° W.

406c. A ship is on course 151°. The following relative bearings are observed: (1) 006°, (2) 109°, (3) 255°, (4) broad on the port bow.

Required.—The bearings from north.

Answers.—(1) 157°, (2) 260°, (3) 046°, (4) 106°.

406d. A ship is on course 244°. The following bearings from north are observed: (1) 041°, (2) 188°, (3) 332°.

Required.—The relative bearings.

Answers.—(1) 157°, (2) 304°, (3) 088°.

406e. The captain of a ship on course 055° wishes to change course when a certain lighthouse is broad on the starboard beam.

Required.—The bearing from north when the course is to be changed.

Answer.— 145°.

407a. Convert the following true directions to grid directions using (1) a convergency of one, (2) a convergency of 0.866. (Give answers to nearest whole degree.)

True	*Latitude*	*Longitude*
157°	N	27° W
353°	N	114° E
118°	S	63° E
042°	S	147° W

Answers.—(1) 184°, 239°, 181°, 255°; (2) 180°, 254°, 173°, 275°.

407b. Convert the following grid directions to true directions using (1) a convergency of 0.629, (2) a convergency of one.

Grid	*Latitude*	*Longitude*
003°	N	174° W
148°	S	9° W
317°	N	64° E
256°	S	155° E

Answers.—(1) 254°, 154°, 357°, 159°; (2) 189°, 157°, 021°, 101°.

CHAPTER V

MEASUREMENT ON THE CELESTIAL SPHERE

501. The celestial sphere.—A glimpse of the sky on a clear night is sufficient to enable an observer to imagine that all of the heavenly bodies are located on the inner surface of a sphere (fig. 501a) of infinite radius with the earth at its center. This imaginary dome is called the **celestial sphere** (fig. 501b) whose north and south **celestial poles** are located by the extension of the earth's axis and whose **celestial equator** (sometimes called **equinoctial**) is formed by projecting the plane of the earth's equator to the celestial sphere. A **celestial meridian** is formed by the intersection of the plane of a terrestrial meridian, extended, and the celestial sphere. It is the arc of a great circle through the poles of the celestial sphere.

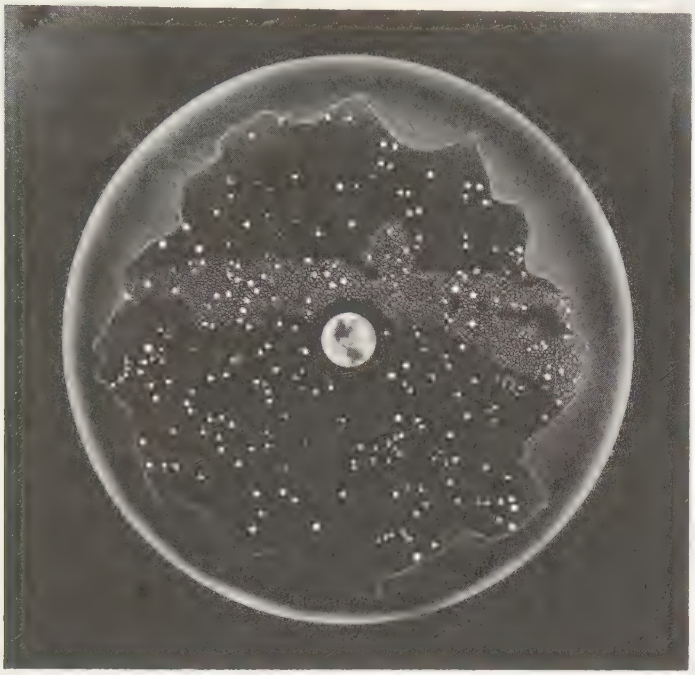

FIGURE 501a.—The celestial sphere.

The point on the celestial sphere vertically overhead of an observer is the **zenith** and the point on the opposite side of the sphere, vertically below him, is the **nadir**. The zenith and nadir are the extremities of a diameter of the celestial sphere through the observer and the common center of the earth and the celestial sphere. The arc of a celestial meridian between the poles is called the **upper branch** if it contains the zenith and the **lower branch** if it contains the nadir. The upper branch is frequently used in navigation and references to a celestial meridian are understood to mean only its upper branch unless otherwise stated. Celestial meridians take the names, as 65° west, of their terrestrial counterparts.

An **hour circle** is a great circle through the celestial poles and a point or body on the celestial sphere. It is similar to a celestial meridian, but moves with the celestial sphere as it rotates about the earth, while a celestial meridian remains fixed with respect to the earth.

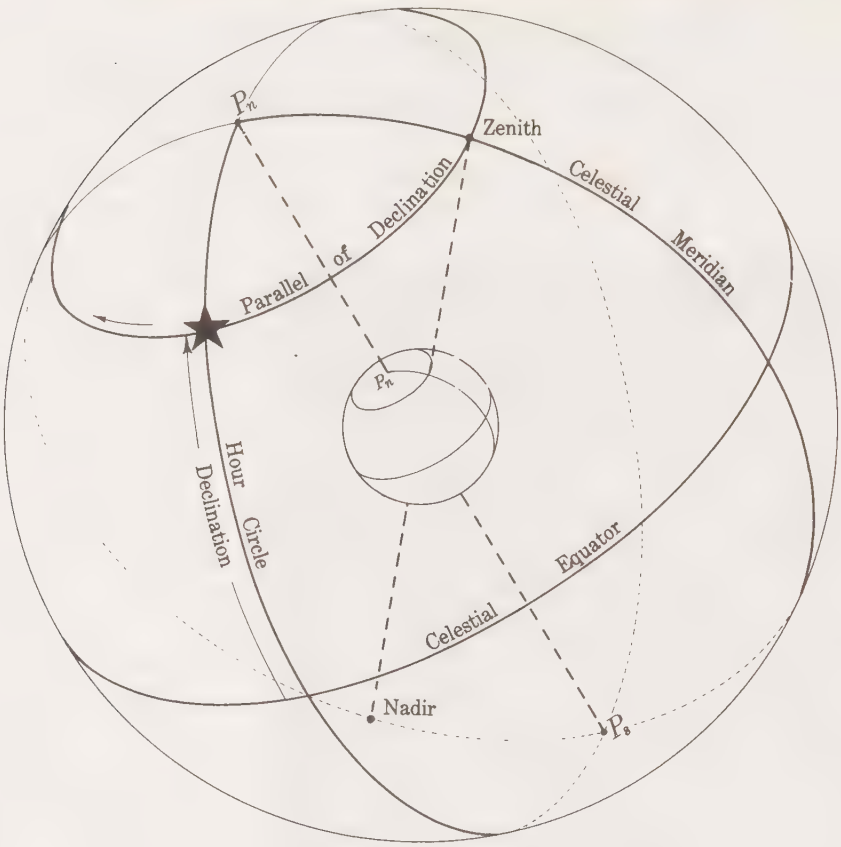

FIGURE 501b.—Elements of the celestial sphere.

The location of a body along its hour circle is defined by the body's angular distance from the celestial equator. This distance, called **declination,** is measured north or south of the celestial equator in degrees, from 0° through 90°, similar to latitude on the earth.

A circle parallel to the celestial equator is called a **parallel of declination,** since it connects all points of equal declination. It is similar to a parallel of latitude on the earth. The path of a celestial body during its daily apparent revolution around the earth is called its **diurnal circle.** It is not actually a circle if a body changes its declination. Since the declination of all navigational bodies is continually changing, the bodies are describing flat spherical spirals as they circle the earth. However, since the change is relatively slow, a diurnal circle and a parallel of declination are usually considered identical.

A point on the celestial sphere may be identified at the intersection of its parallel of declination and its hour circle. The parallel of declination is identified by the declination.

Two basic methods of locating the hour circle are in use. Its angular distance west of a reference hour circle through a point on the celestial sphere called the **vernal equinox** or **first point of Aries** is called **sidereal hour angle** (**SHA**) (fig. 501c). This angle measured eastward from the vernal equinox is called **right ascension,** and is usually expressed in time units.

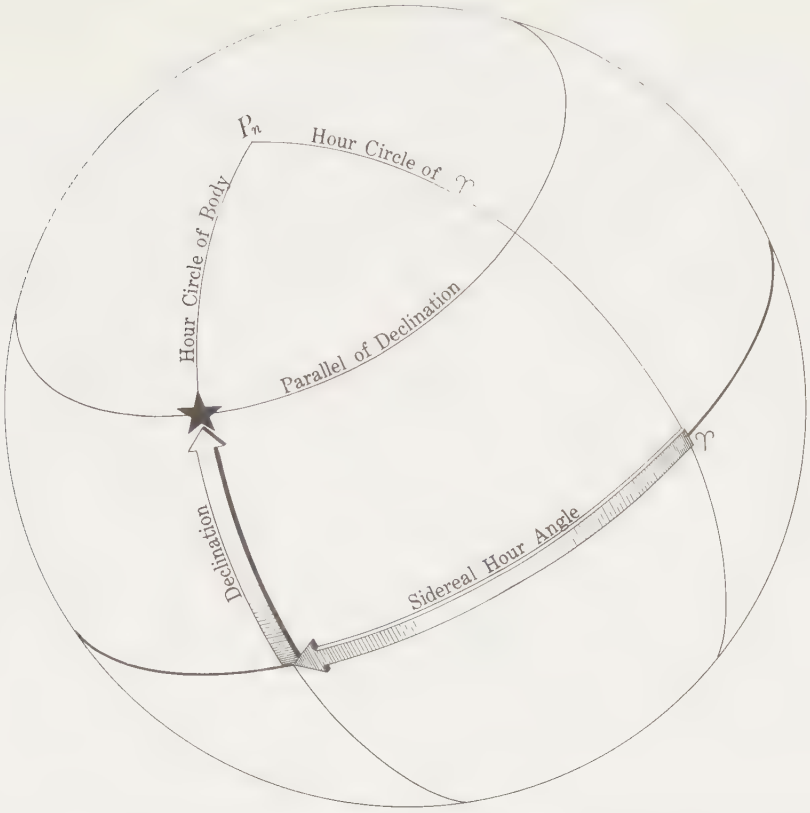

FIGURE 501c.—A point on the celestial sphere can be located by its declination and sidereal hour angle.

The second method of locating the hour circle is to indicate its angular distance west of a celestial meridian (fig. 501d). If the Greenwich celestial meridian is used as the reference, the angular distance is called **Greenwich hour angle** (**GHA**), and if the meridian of the observer, it is called **local hour angle** (**LHA**). It is sometimes more convenient to measure LHA either eastward or westward, as longitude is measured on the earth, in which case it is called **meridian angle** (**t**). These coordinates are discussed further in article 504.

A point on the celestial sphere may also be located by means of **altitude** and **azimuth,** coordinates based upon the horizon as the primary great circle, instead of the celestial equator. This system is discussed in article 506.

Two additional systems used by astronomers are based upon the ecliptic (art. 502) and the galactic equator (the approximate mid great circle of the galaxy). The coordinates of the ecliptic system are **celestial latitude** and **celestial longitude** and those of the galactic system are **galactic latitude** and **galactic longitude.**

502. Apparent motion of celestial bodies.—To a terrestrial observer the earth seems to be stationary and the various celestial bodies appear to be in continual motion. It is this **apparent motion,** or motion relative to the earth, that concerns the navigator primarily.

The daily motion of the various bodies due to the rotation of the earth is the most conspicuous movement. Even a casual observer, however, soon notes that the various celestial bodies do not maintain the same positions relative to each other.

FIGURE 501d.—A point on the celestial sphere can be located by its declination and hour angle.

That is, while the celestial sphere appears to rotate about its axis, making one revolution about the apparently stationary earth each day, the various celestial bodies are changing their positions on the sphere.

If the rotation of the earth on its axis could be stopped, so that the daily apparent rotation of the celestial sphere would cease, the motions of the various bodies relative to each other would be more apparent. The stars would appear almost stationary. This is why they are sometimes called "fixed stars." They form a nearly stationary background which serves as a convenient reference for other motions.

The sun would appear to move eastward about 1° per day, completing its trip around the celestial sphere in 1 year. The motion is not along the celestial equator, but along another great circle, called the **ecliptic,** which is inclined to the celestial equator at an angle of about 23°27′ (fig. 502a). This great circle lies in the plane of the earth's orbit around the sun, since it is this *actual* motion that causes the *apparent* motion of the sun.

The moon would appear to make one trip around the celestial sphere each month, following closely the path of the sun. The planets would appear to move erratically, but keeping close to the ecliptic.

The two points at which the ecliptic crosses the celestial equator are called **equinoxes** (meaning "equal nights"), since days and nights are of equal length when the sun is at these points. The sun is at one of these points (♈) about March 21. This is called the **vernal** (spring) **equinox, first point of Aries,** or **March equinox.**

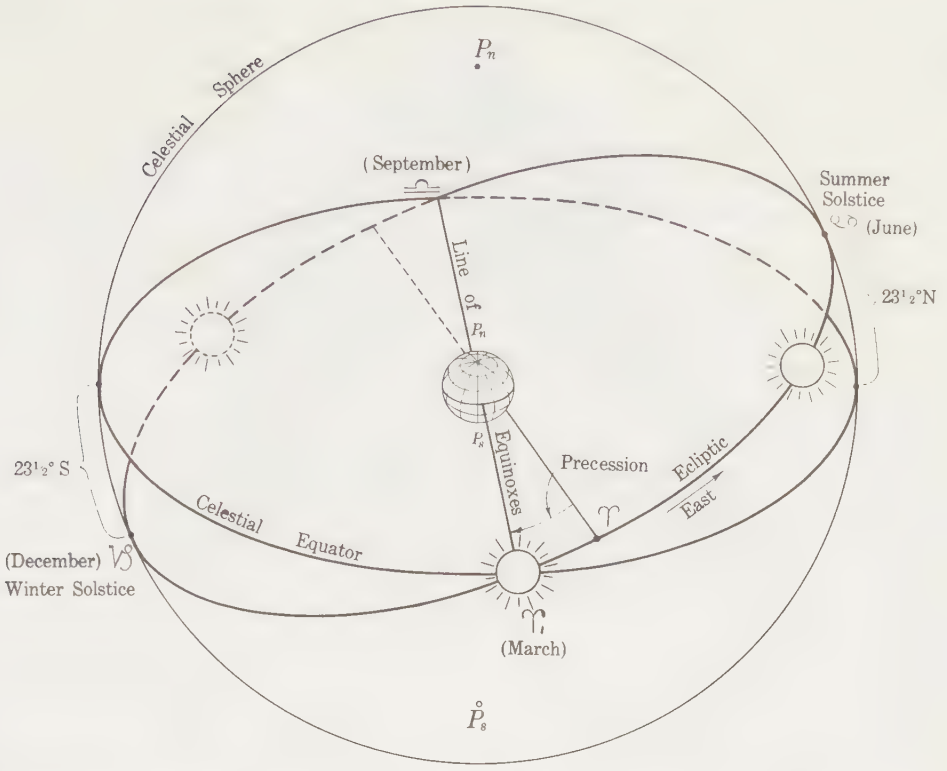

FIGURE 502a.—Elements of the ecliptic, along which the sun appears to move during 1 year.

Since the sun is on the celestial equator at this time, its declination is 0°. As it continues eastward, it arrives about June 21 at one of the points of maximum separation of the ecliptic and celestial equator. This is called the **summer solstice,** sometimes called **June solstice.** At this time the declination of the sun reaches its maximum value of about 23°27′ N, and since the ecliptic and celestial equator are parallel at this point, the *change* in declination of the sun is momentarily zero, increasing slowly on each side of this point. Hence, the name *solstice*, meaning "sun standing still."

Continuing on, the sun arrives at the **autumnal** or **September equinox** about September 23, when the declination is again 0° and the days and nights are again of equal length. In another 3 months it arrives at the **winter** or **December solstice** about December 22, when the declination is again maximum, but on the opposite side of the celestial equator. By March 21 it has arrived back at the vernal equinox, completing the cycle.

The terms *equinox* and *solstice* refer both to the points indicated and the times at which the sun is at these points.

503. Coordinate systems.—Various systems of coordinates on the celestial sphere, all of them similar to the familiar latitude and longitude on the earth, were discussed briefly in article 501. Of these, the navigator is rarely concerned with any but the celestial equator system and the horizon system. The former is but an extension to the celestial sphere of the geographical system of the earth. The latter is a similar system in which the horizon replaces the celestial equator as the primary great circle, and the zenith and nadir are the poles. These two systems are the almost constant companions of the celestial navigator.

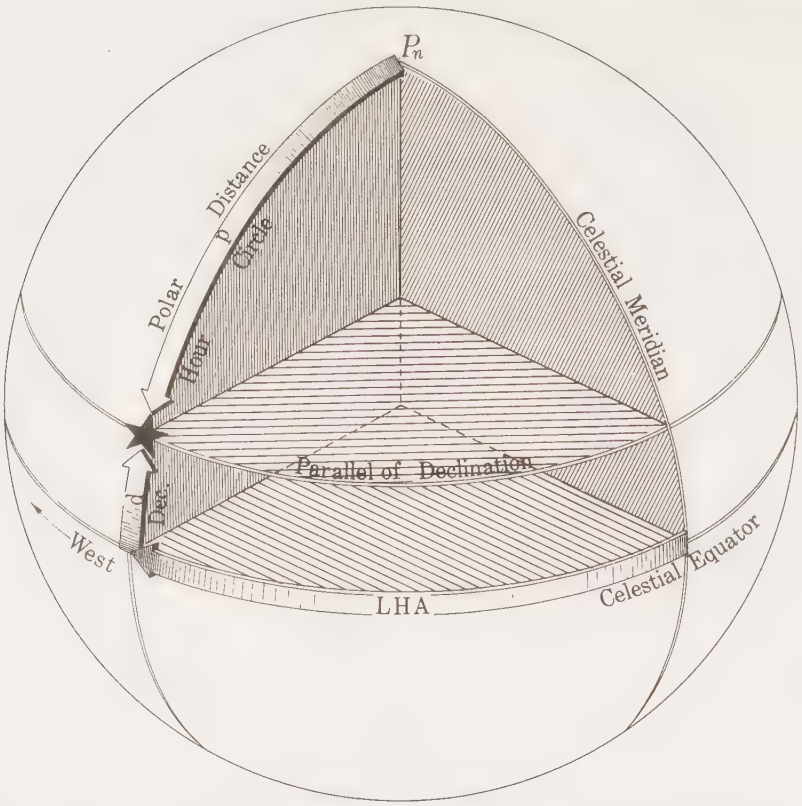

FIGURE 504a.—The celestial equator system of coordinates, showing measurement of declination, polar distance, and local hour angle.

504. The celestial equator system of coordinates.—If the familiar graticule of latitude and longitude lines is expanded until it reaches the celestial sphere of infinite radius, it forms the basis of the celestial equator system of coordinates, as explained in article 501. On the celestial sphere the familiar *latitude* becomes **declination** (**d**), and *longitude*, measured always toward the west, through 360°, becomes **sidereal hour angle** (**SHA**) if measured from the vernal equinox.

Declination (**d**) is angular distance north or south of the celestial equator (d in fig. 504a). It is measured along an hour circle, from 0° at the celestial equator through 90° at the celestial poles, and is labeled N or S to indicate the direction of measurement. All points having the same declination lie along a **parallel of declination.**

Polar distance (**p**) is angular distance from a celestial pole, or the arc of an hour circle between the celestial pole and a point on the celestial sphere. It is measured along an hour circle and may vary from 0° to 180°, since either pole may be used as the origin of measurement. It is usually considered the complement of declination, though it may be either 90°−d or 90°+d, depending upon the pole used.

Local hour angle (**LHA**) is angular distance west of the local celestial meridian, or the arc of the celestial equator between the upper branch of the local celestial meridian and the hour circle through a point on the celestial sphere, measured westward from the local celestial meridian, through 360°. It is also the similar arc of the parallel of declination and the angle at the celestial pole, similarly measured. If the Greenwich (0°) meridian is used as the reference, instead of the local meridian, the expression **Greenwich hour angle** (**GHA**) is applied. It is sometimes convenient to measure the arc or angle in *either* an easterly or westerly direction from the local meridian, through 180°, when it is called **meridian angle** (**t**) and labeled E or W to indicate the direction of measurement. All bodies or other points having the same hour angle lie along the same **hour circle.**

The **time diagram** shown in figure 504b illustrates the relationship between the various hour angles and meridian angle. The circle is the celestial equator as seen from above the *south* pole, with the upper branch of the observer's meridian (P_sM) at the top. The radius P_sG is the Greenwich meridian, $P_s\Upsilon$ the hour circle of the vernal equinox, and P_sS and P_sS' the hour circles of celestial bodies to the *west* and *east*, respectively, of the observer's celestial meridian. Note that when LHA is less than 180°, t is numerically the same and is labeled W, but that when LHA is greater than 180°, t=360°—LHA and is labeled E. In figure 504b arc *GM* is the longitude, which in this case is west. The relationships shown apply equally to other arrangements of radii, except for relative magnitudes of the quantities involved.

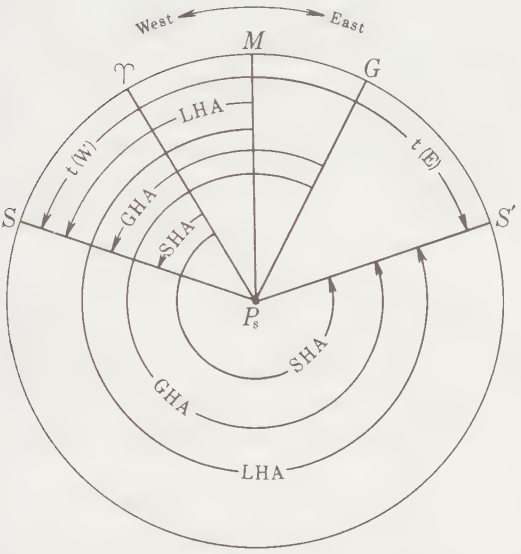

FIGURE 504b.—Time diagram. Local hour angle, Greenwich hour angle, and sidereal hour angle are measured westward through 360°. Meridian angle is measured eastward or westward through 180° and labeled E or W to indicate the direction of measurement.

505. The horizons.—The second set of celestial coordinates with which the navigator is directly concerned is based upon the **horizon** as the primary great circle. However, since several different horizons are defined, these should be thoroughly understood before proceeding with a consideration of the horizon system of coordinates.

The line where earth and sky appear to meet is called the **visible** or **apparent horizon.** On land this is usually an irregular line unless the terrain is level. At sea the visible horizon appears very regular and often very sharp. However, its position relative to the celestial sphere depends primarily upon (1) the refractive index of the air, and (2) the height of the observer's eye above the surface.

Figure 505 shows a cross section of the earth and celestial sphere through the position of an observer at A above the surface of the earth. A straight line through A and the center of the earth O is the vertical of the observer, and contains his zenith (Z) and nadir (Na). A plane perpendicular to the true vertical is a horizontal plane, and its intersection with the celestial sphere is a horizon. It is the **celestial horizon** if the plane passes through the center of the earth, the **geoidal horizon** if it is tangent to the earth, and the **sensible horizon** if it passes through the eye of the observer at A. Since the radius of the earth is considered negligible with respect to that of the celestial sphere, these horizons become superimposed, and most measurements are referred only to the celestial horizon. This is sometimes called the **rational horizon** from the latin word "ratio," reckoning.

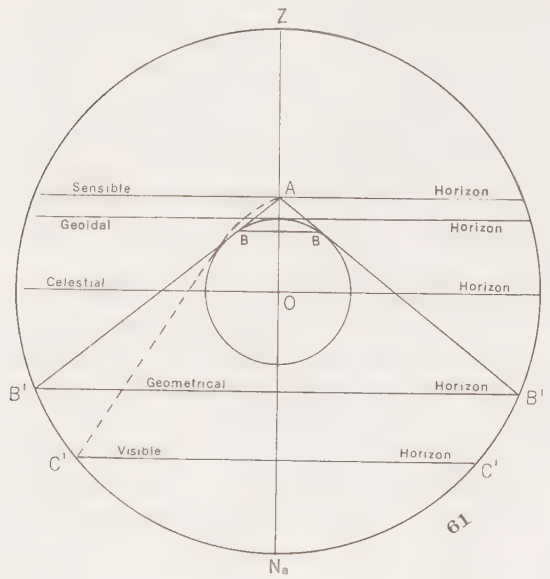

FIGURE 505.—The horizons used in navigation.

If the eye of the observer is at the surface of the earth, his visible horizon coincides with the plane of the geoidal horizon; but when elevated above the surface, as at A, his eye becomes the vertex of a cone which, neglecting refraction, is tangent to the earth at the small circle BB, and which intersects the celestial sphere in $B'B'$, the **geometrical horizon.** This expression is sometimes—but less appropriately—applied to the celestial horizon.

Because of refraction (arts. 805 and 806), the visible horizon $C'C'$ appears above but is actually slightly below the geometrical horizon as shown in figure 505.

For any elevation above the surface, the celestial horizon is usually *above* the geometrical and visible horizons, the difference increasing as elevation increases. It is thus possible to observe a body which is above the visible horizon but below the celestial horizon. That is, the body's altitude is negative and its zenith distance is greater than 90° (art. 506).

506. The horizon system of coordinates is based upon the celestial horizon as the primary great circle, and a series of secondary **vertical circles,** which are great circles through the zenith and nadir of the observer and hence perpendicular to his horizon. Thus, the celestial horizon is similar to the equator, and the vertical circles are similar to meridians, but with one important difference. The celestial horizon and vertical circles are dependent upon the position of the observer and hence move with him as he changes position, while the primary and secondary great circles of both the geographical and celestial equator systems are independent of the observer. The horizon and celestial equator systems coincide for an observer at the geographical pole of the earth, and are mutually perpendicular for an observer on the equator. At all other places the two are oblique.

The vertical circle through the north and south points of the horizon passes through the poles of the celestial equator system of coordinates. One of these poles (having the same name as the latitude) is above the horizon and is called the **elevated pole.** The other, called the **depressed pole,** is below the horizon. Since this vertical circle is a great circle through the celestial poles, and includes the zenith of the observer, it is

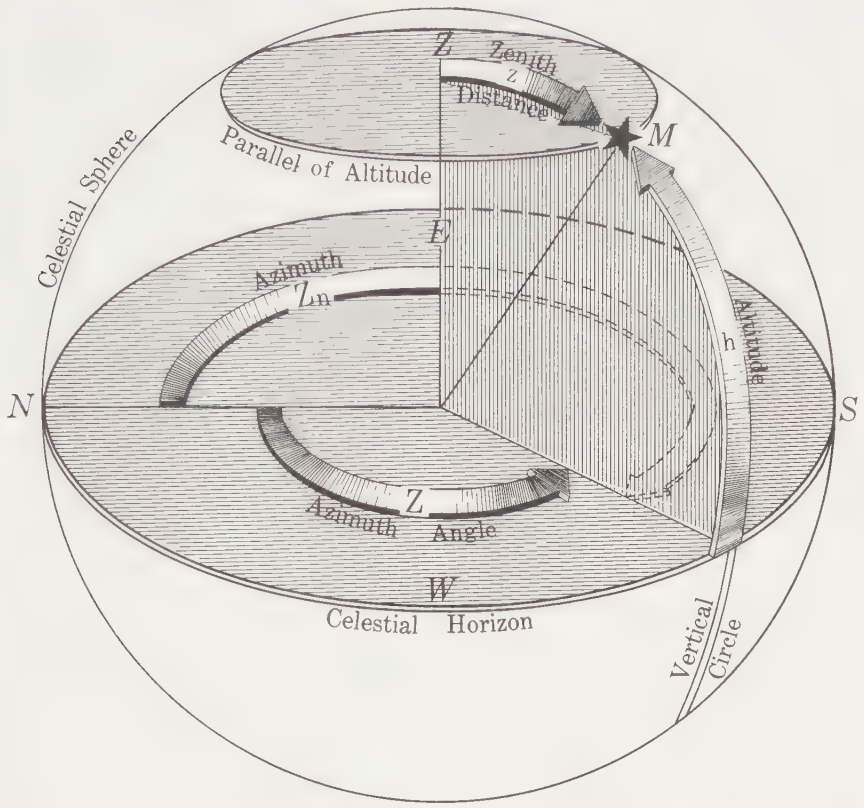

FIGURE 506.—The horizon system of coordinates, showing measurement of altitude, zenith distance, azimuth, and azimuth angle.

also a celestial meridan. In the horizon system it is called the **principal vertical circle.** The vertical circle through the east and west points of the horizon, and hence perpendicular to the principal vertical circle, is called the **prime vertical circle,** or simply the **prime vertical.**

As shown in figure 506, **altitude** is angular distance above the horizon. It is measured along a vertical circle, from 0° at the horizon through 90° at the zenith. Altitude measured from the visible horizon may exceed 90° because of the dip of the horizon, as shown in figure 505. Angular distance below the horizon, called **negative altitude,** is provided for by including certain negative altitudes in some tables for use in celestial navigation, such as Pub. No. 249. All points having the same altitude lie along a **parallel of altitude** or **almucantar.**

Zenith distance (z) is angular distance from the zenith, or the arc of a vertical circle between the zenith and a point on the celestial sphere. It is measured along a vertical circle from 0° through 180°. It is usually considered the complement of altitude. For a body above the celestial horizon it is equal to 90°−h and for a body below the celestial horizon it is equal to 90°−(−h) or 90°+h; or 90°+a negative altitude.

The horizontal direction of a point on the celestial sphere, or the bearing of the geographical position is called **azimuth** or **azimuth angle** depending upon the method of measurement. In both methods it is an arc of the horizon (or parallel of altitude) or an angle at the zenith. It is **azimuth** (**Zn**) if measured clockwise through 360°, starting at the north point on the horizon; and **azimuth angle** (**Z**) if measured *either* clockwise or counterclockwise through 180°, starting at the north point of the horizon in north latitude and the south point of the horizon in south latitude.

507. Diagram on the plane of the celestial meridian.—From a point outside the celestial sphere (if this were possible) and over the celestial equator, at such a distance that the view would be orthographic, the great circle appearing as the outer limit would be a celestial meridian. Other celestial meridians would appear as ellipses. The celestial equator would appear as a diameter 90° from the poles, and parallels of declination as straight lines parallel to the equator.

A number of useful relationships can be demonstrated by drawing a **diagram on the plane of the celestial meridian** showing this orthographic view. Arcs of circles can be substituted for the ellipses without destroying the basic relationships. Refer to figure 507a. In the lower diagram the circle represents the celestial meridian, QQ' the celestial equator, Pn and Ps the north and south celestial poles, respectively. If a star has a declination of 30° N, an angle of 30° can be measured from the celestial equator, as

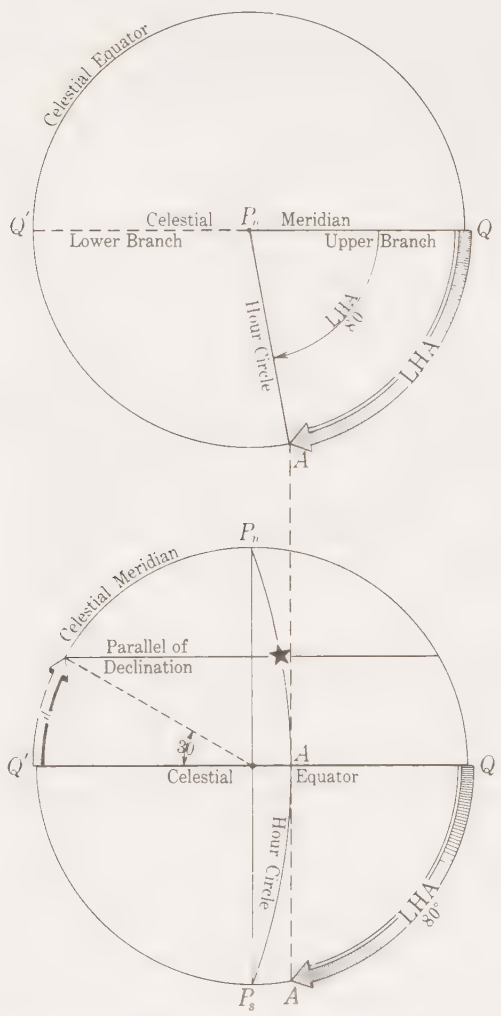

FIGURE 507a.—Measurement of celestial equator system of coordinates.

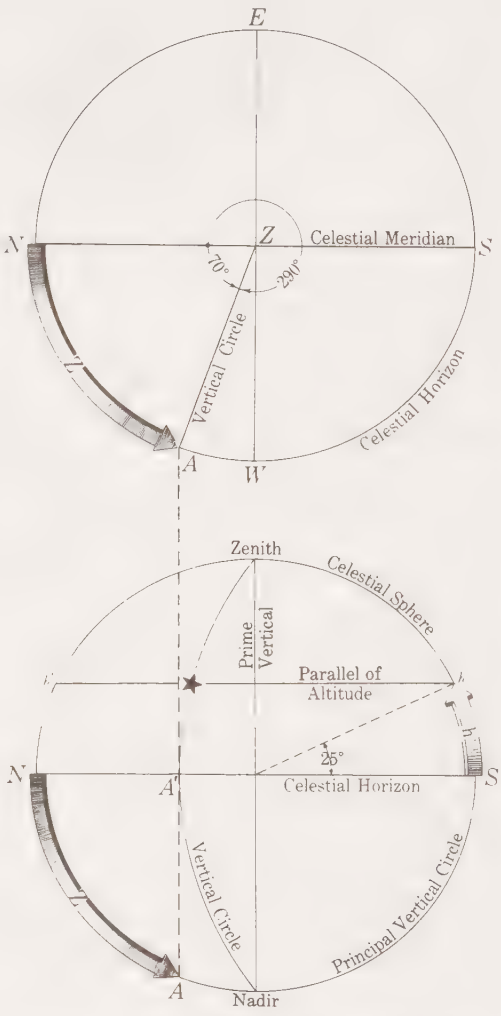

FIGURE 507b.—Measurement of horizon system of coordinates.

shown. It could be measured either to the right or left, and would have been toward the south pole if the declination had been south. The parallel of declination is a line through this point and parallel to the celestial equator. The star is somewhere on this line (actually a circle viewed on edge).

To locate the hour circle, draw the upper diagram so that *Pn* is directly above *Pn* of the lower figure (in line with the polar axis *Pn Ps*), and the circle is of the same diameter as that of the lower figure. This is the plan view, looking down on the celestial sphere from the top. The circle is the celestial equator. Since the view is from above the *north* celestial pole, west is clockwise. The diameter *QQ'* is the celestial meridian shown as a circle in the lower diagram. If the *right* half is considered the upper branch, local hour angle is measured clockwise from this line to the hour circle, as shown. In this case the LHA is 80°. The intersection of the hour circle and celestial equator, point *A*, can be projected down to the lower diagram (point *A'*) by a straight line parallel to the polar axis. The elliptical hour circle can be represented approximately by an arc of a circle through *A'*, *Pn*, *Ps*. The center of this circle is somewhere along the celestial equator line *QQ'*, extended if necessary. It is usually found by trial and error. The intersection of the hour circle and parallel of declination locates the star.

Since the upper diagram serves only to locate point *A'* in the lower diagram, the two can be combined. That is, the LHA arc can be drawn in the lower diagram, as shown, and point *A* projected *upward* to *A'*. In practice, the upper diagram is not drawn, being shown here for illustrative purposes only.

In this example the star is on that half of the sphere toward the observer, or the *western* part. If LHA had been greater than 180°, the body would have been on the *eastern* or "back" side.

From the east or west point over the celestial horizon, the orthographic view of the horizon system of coordinates would be similar to that of the celestial equator system from a point over the celestial equator (fig. 507a), since the celestial meridian is also the principal vertical circle. The horizon would appear as a diameter, parallels of altitude as straight lines parallel to the horizon, the zenith and nadir as poles 90° from the horizon, and vertical circles as ellipses through the zenith and nadir, except for the principal vertical circle, which would appear as a circle, and the prime vertical, which would appear as a diameter perpendicular to the horizon.

A celestial body can be located by altitude and azimuth in a manner similar to that used with the celestial equator system. If the altitude is 25°, this angle is measured from the horizon toward the zenith and the parallel of altitude is drawn as a straight line parallel to the horizon, as shown at *hh'* in the lower diagram of figure 507b. The plan view from above the zenith is shown in the upper diagram. If north is taken at the left, as shown, azimuths are measured clockwise from this point. In the figure the azimuth is 290° and the azimuth angle is N 70° W. The vertical circle is located by measuring either arc. Point *A* thus located can be projected vertically downward to *A'* on the horizon of the lower diagram, and the vertical circle represented approximately by the arc of a circle through *A'* and the zenith and nadir. The center of this circle is on *NS*, extended if necessary. The body is at the intersection of the parallel of altitude and the vertical circle. Since the upper diagram serves only to locate *A'* on the lower diagram, the two can be combined, point *A* located on the lower diagram and projected upward to *A'*, as shown. Since the body of the example has an azimuth greater than 180°, it is on the western or "front" side of the diagram.

Since the celestial meridian appears the same in both the celestial equator and horizon systems, the two diagrams can be combined and, if properly oriented, a body can be located by one set of coordinates, and the coordinates of the other system can be determined by measurement.

Refer to figure 507c. By convention, the zenith is shown at the top and the north point of the horizon at the left. The west point on the horizon is at the center, and the east point directly behind it. In the figure the latitude is 37° N. Therefore, the zenith is 37° north of the celestial equator. Since the zenith is established at the top of the dia-

gram, the equator can be found by measuring an arc of 37° toward the south, along the celestial meridian. If the declination is 30° N andthe LHA is 80°, the body can be located as described above.

The altitude and azimuth can be determined by the reverse process to that described above. Draw a line *hh'* through the body and parallel to the horizon, *NS*. The altitude, 25°, is found by measurement, as shown. Draw the arc of a circle through the body and the zenith and nadir. From *A'*, the intersection of this arc with the horizon, draw a vertical line intersecting the circle at *A*. The azimuth, N 70° W, is found by measurement, as shown. The prefix N is applied to agree with the latitude. The body is left (*north*) of *ZNa*, the prime vertical circle. The suffix W applies because the LHA, 80°, shows that the body is west of the meridian.

If altitude and azimuth are given, the body is located as described above. The parallel of declination is then drawn parallel to *QQ'*, the celestial equator, and the declination determined by measurement. Point *L'* is located by drawing the arc of a circle through *Pn*, the star, and *Ps*. From *L'* a line is drawn perpendicular to *QQ'*, locating *L*. The meridian angle is then found by measurement. The declination is known to be north because the body is between the celestial equator and the north celestial pole. The meridian angle is west to agree with the azimuth angle, and hence LHA is numerically the same.

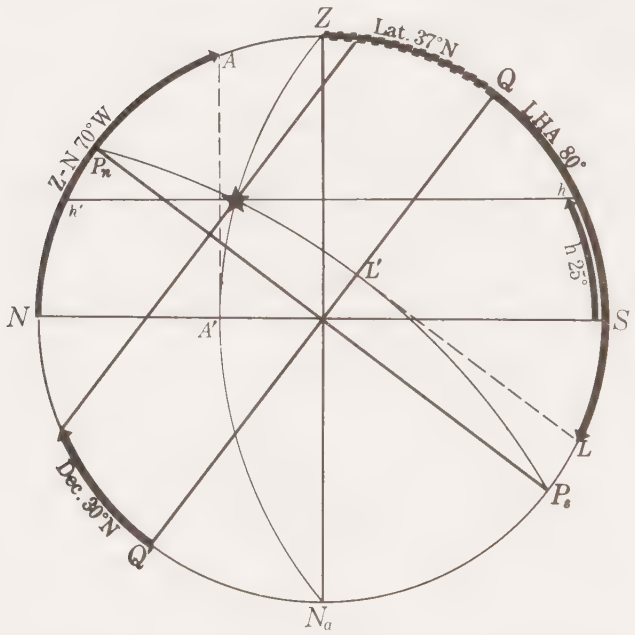

FIGURE 507c.—Diagram on the plane of the celestial meridian.

Since *QQ'* and *PnPs* are perpendicular, and *ZNa* and *NS* are also perpendicular, arc *NPn* is equal to arc *ZQ*. That is, *the altitude of the elevated pole is equal to the declination of the zenith, which is equal to the latitude.* This relationship is the basis of the method of determining latitude by an observation of Polaris.

The diagram on the plane of the celestial meridian is useful in approximating a number of relationships.

508. The navigational triangle.—A triangle formed by arcs of great circles of a sphere is called a **spherical triangle.** A spherical triangle on the celestial sphere is called a **celestial triangle.** The spherical triangle of particular significance to navigators is

called the **navigational triangle.** It is formed by arcs of a celestial meridian, an hour circle, and a vertical circle. Its vertices are the elevated pole, the zenith, and a point on the celestial sphere (usually a celestial body). The terrestrial counterpart is also called a navigational triangle, being formed by arcs of two meridians and the great circle connecting two places on the earth, one on each meridian. The vertices are the two places and a pole. In great-circle sailing these places are the point of departure and the destination. In celestial navigation they are the **assumed position** (**AP**) of the observer and the **geographical position** (**GP**) of the body (the place having the body in its zenith). The GP of the sun is sometimes called the **subsolar point,** that of the moon the **sublunar point,** that of a satellite (either natural or artificial) the **subsatellite point,** and that of a star its **substellar** or **subastral point.** When used to solve a celestial observation, either the celestial or terrestrial triangle may be called the **astronomical triangle.**

The navigational triangle is shown in figure 508a on a diagram on the plane of the celestial meridian, labeled as in article 507, but with the hour circle and vertical circle properly shown as ellipses. The earth is at the center, *O*. The star is at *M*, *dd'* is its parallel of declination, and *hh'* its altitude circle.

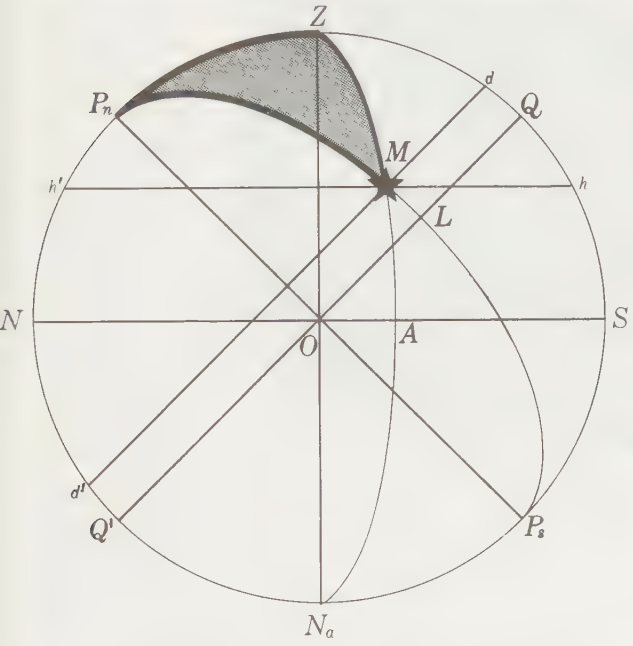

FIGURE 508a.—The navigational triangle.

In the figure, arc *QZ* of the celestial meridian is the latitude of the observer, and *PnZ*, one side of the triangle, is the **colatitude.** Arc *AM* of the vertical circle is the altitude of the body, and side *ZM* of the triangle is the zenith distance, or **coaltitude.** Arc *LM* of the hour circle is the declination of the body, and side *PnM* of the triangle is the polar distance, or **codeclination.**

The angle at the elevated pole, *ZPnM*, having the hour circle and the celestial meridian as sides, is the meridian angle, t. The angle at the zenith, *PnZM*, having the vertical circle and that arc of the celestial meridian which includes the elevated pole as sides, is the azimuth angle. The angle at the celestial body, *ZMPn*, having the hour circle and the vertical circle as sides, is the **parallactic angle** (sometimes called **position angle**). It is rarely used in celestial navigation.

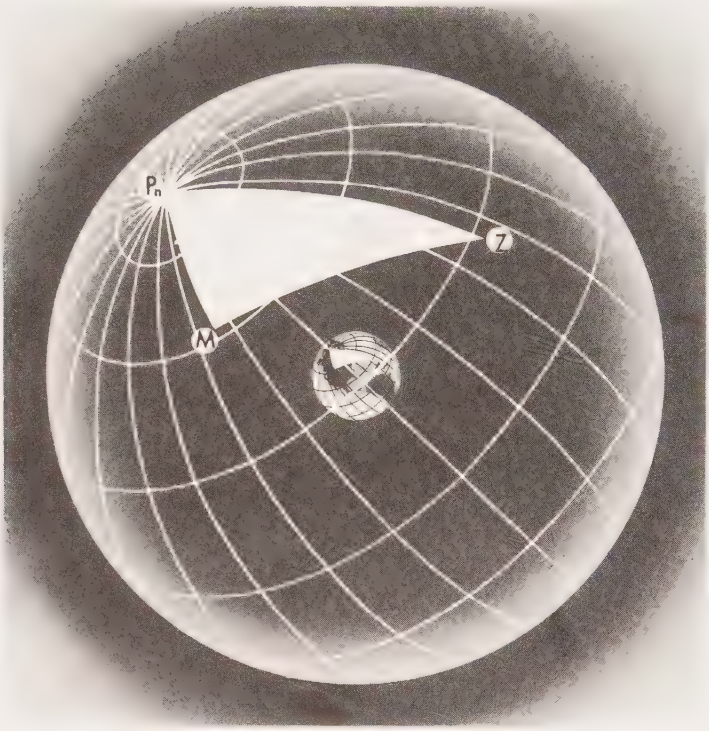

FIGURE 508b.—The navigational triangle in perspective.

CHAPTER VI

TIME MEASUREMENTS AND CONVERSIONS

601. Introduction.—Time serves to regulate affairs aboard ship, as it does ashore. But to the navigator, it has additional significance. It is not enough to know *where* the ship is, was, or might be located in the future. The navigator wants to know *when* the various positions were or can reasonably be expected to be occupied. Time serves as a measure of progress. By considering the time at which a ship occupied various positions in the past, and by comparing the speed and various conditions it has encountered with those anticipated for the future, the skillful navigator can predict with reasonable accuracy the time of arrival at various future positions. Time can serve as a measure of safety, for it indicates when a light or other aid to navigation might be sighted, and if it is not seen by a certain time, the navigator knows he has cause for concern.

To the celestial navigator, time is of added significance, for it serves as a measure of the *phase* of the earth's rotation. That is, it indicates the position of the celestial bodies relative to meridians on the earth. Until an accurate *measure* of time became available at sea, longitude could not be found.

Very small *intervals* of time are used in certain electronic navigational aids, such as radar and Loran.

Whatever the type of navigation, a thorough mastery of the subject of time is important to the navigator. The use of a time diagram (art. 504) may help in understanding the principles or solution of the problems of this chapter.

602. Kinds of time.—As a measure of part of a day, time can be stated in a number of different ways. At any given moment, the time depends upon (1) the point on the celestial sphere used as reference, (2) the reference meridian on the earth, and (3) the somewhat arbitrary starting point of the day.

When the sun is used as the celestial reference point, **solar time** results. If the actual sun observable in the sky is used, **apparent solar time** is involved, and if a fictitious **mean sun** is used to provide a time having an almost constant rate, **mean solar time** results. Time reckoned by use of the first point of Aries (♈) as the celestial reference point is called **sidereal time.** Use of the moon as the celestial reference point provides a variable-length **lunar day,** the basis of **lunar time,** which is useful in tide prediction and analysis. Because of its application, a lunar day is sometimes called a **tidal day.** It averages about 24^h50^m (mean solar units) in length.

If the meridian of the observer is used as the terrestrial reference, **local time** is involved. If a **zone** or **standard meridian** is used as the **time meridian** for mean solar time over an area, **zone** or **standard time** results. Use of a meridian farther east than would normally be used, so that the period of daylight is shifted later in the day, produces a form of zone time called **daylight saving** or **summer time.** Time based upon the Greenwich meridian is called **Greenwich time. Greenwich mean time** (**GMT**) is of particular interest to a navigator because it is the principal entering argument for the almanacs.

One complete revolution of the earth with respect to a celestial reference point is called a **day**. In modern usage every kind of solar time has its zero or starting point at **midnight,** when the celestial reference point is directly over the *lower branch* of the

terrestrial reference meridian. This has not always been so. Until January 1, 1925, the **astronomical day** began at *noon*, 12 hours *later* than the start of the calendar day of the same date. The **nautical day** began at *noon*, 12 hours *earlier* than the calendar day, or 24 hours earlier than the astronomical day of the same date. The **sidereal day** begins at **sidereal noon,** when the first point of Aries is over the *upper* branch of the reference meridian. There is no sidereal date.

603. Expressing time.—Time is customarily expressed in time units, from 0^h through 24^h. To the nearest 1^m it is generally stated by navigators in a four-digit unit without punctuation. Thus, 0000 is midnight at the start of the day. One minute later the time is 0001. Half an hour after the start of the day the time is 0030, at one hour the time is 0100, at one hour and four minutes it is 0104, at 19 minutes after noon (solar time) it is 1219, at four hours and 23 minutes after (solar) noon it is 1623, etc. The term "hours" is sometimes used with the four-digit system to indicate that the number refers to the time or "hour" of the day. However, in those few occasions when any reasonable doubt may exist as to whether time is indicated, the fact can better be indicated in another way. Thus, the expression "1600 hours" to indicate "1600" or "16 hours" is not strictly correct, and is better avoided. **Watch time** (**WT**), indicated by a watch or clock having a 12-hour dial, and **chronometer time** (**C**) are expressed on a 12-hour basis, with designations AM (ante meridian) and PM (post meridian), as in ordinary civil life ashore.

In contrast, a time interval is expressed as hours and minutes, as 5^h26^m. When either the time of day or a time interval is given to seconds, this same form is used, as $21^h15^m18^s$. The kind of time may be indicated, usually by abbreviation.

When a time interval is to be added to or subtracted from a time, the solution can be arranged conveniently in tabular form.

Example 1.—What is the time and date $14^h36^m53^s$ after $21^h14^m18^s$ on July 24?

Solution.—

$$\begin{array}{r} 21^h14^m18^s \text{ July } 24 \\ 14^h36^m53^s \\ \hline 35^h51^m11^s \text{ July } 24 \\ =11^h51^m11^s \text{ July } 25 \end{array}$$

The fact that the sum of hours exceeds 24 is an indication that the date increases by one. Similarly, in *subtracting* an interval, the date is one day earlier if 24^h must be added to the time before the subtraction can be made. That is, since 2400 of one day is 0000 of the following day, one might say that 2700 on one day is 2700−2400= 0300 on the following day. In the example above, $11^h51^m11^s$ on July 25 is the same as $11^h51^m11^s+24^h00^m00^s=35^h51^m11^s$ on July 24.

Date is sometimes expressed as an additional unit of the time sequence. Thus, $21^h14^m18^s$ on July 24 might be stated $24^d21^h14^m18^s$. This system is of particular value when an interval of several days is to be added or subtracted.

Example 2.—What is the time and date $9^d16^h35^m04^s$ before $5^h11^m33^s$ on September 15?

Solution.—

$$\begin{array}{r} 15^d05^h11^m33^s \\ 9^d16^h35^m04^s \\ \hline 5^d12^h36^m29^s \text{ or } 12^h36^m29^s \text{ on Sept. } 5. \end{array}$$

By this method the month and day, if of significance, are recorded separately, or they, too, can be added to the sequence.

Example 3.—What is the time and date 3 years, 6 months, 25 days, 12 hours, 19 minutes, and 44 seconds after $7^h52^m24^s$ on November 14, 1958?

Solution.—

$$\begin{array}{r} 1958^{y}11^{m}14^{d}07^{h}52^{m}24^{s} \\ \quad 3^{y}06^{m}25^{d}12^{h}19^{m}44^{s} \\ \hline 1962^{y}06^{m}08^{d}20^{h}12^{m}08^{s} \end{array} = 20^{h}12^{m}08^{s} \text{ on June 8, 1962.}$$

Since a month may contain a variable number of days, both the months and days should be solved together. Thus, in the example above, the answer would be 17 months, 39 days. If 12 months are converted to one year, this becomes five months, 39 days. Since the fifth month is May, this might be stated as May 39. Since there are 31 days in May, this is 39—31=8 days into the next month, or June 8.

A simpler method of determining the number of elapsed *days* between any two dates is to use the **Julian day** of each date, if the information is available. This also eliminates possible error due to change of calendar if long intervals are involved. The Julian day is the consecutive number of the day starting at 1200 on January 1, 4713 BC. Julian day is listed in the *American Ephemeris and Nautical Almanac.*

604. Time and arc.—The time of day is an indication of the interval since the day began. One day represents one complete rotation of 360° of the earth with respect to a selected celestial point. Each day is divided into 24 **hours** of 60 **minutes**, each minute having 60 **seconds.** Thus, each day has 24×60=1,440 minutes or 1,440×60=86,400 seconds. This is time regardless of the celestial reference point used, and since the various references are in motion with respect to each other, as "seen" from the earth, apparent solar, mean solar, and sidereal days are of different lengths. Since they all have the same number and kind of fractional parts, these parts are themselves of different length in the different kinds of time. Mean solar units are customarily used to indicate time intervals. The smallest unit normally used in celestial navigation is the second, but in some electronic equipment the **millisecond** (one-thousandth of a second), **microsecond** (one-millionth of a second), and the **millimicrosecond** or **nanosecond** (one-billionth of a second) are used.

Time of day is an indication of the *phase* of rotation of the earth. That is, it indicates how much of a day has elapsed, or what part of a rotation has been completed. Thus, at zero hours the day begins. One hour later, the earth has turned through 1/24 of a day, or 1/24 of 360°, or $\frac{360°}{24}=15°$. Six hours after the day begins, it has turned through 6/24=1/4 day, or $\frac{360°}{4}=90°$. Twelve hours after the start of the day, the day is half gone, having turned through 180°. Smaller intervals can also be stated in angular units, for since one hour or 60 minutes is equivalent to 15°, one minute of time is equivalent to $\frac{15°}{60}=0°.25=15'$, and one second of time is equivalent to $\frac{15'}{60}=0'.25=15''$. Thus,

Time	*Arc*
$1^{d}=24^{h}$	$=360°=1$ circle
$60^{m}=1^{h}$	$=15°$
$4^{m}=1°$	$=60'$
$60^{s}=1^{m}$	$=15'$
$4^{s}=1'$	$=60''$
$1^{s}=15''$	$=0'.25$

Any time interval can be expressed as an angle of rotation, and vice versa. Interconversion of these units can be made by the relationships indicated above.

To convert time to arc:

1. Multiply the hours by 15 to obtain degrees.

2. Divide the minutes of time by four to obtain degrees, and multiply the remainder by 15 to obtain minutes of arc.

3. Divide the seconds of time by four to obtain minutes and tenths of minutes of arc, or multiply the remainder by 15 to obtain seconds of arc.

4. Add degrees, minutes, and tenths (or seconds).

Example 1.—Convert $14^h21^m39^s$ to arc units.

Solution.—

(1) $14^h \times 15 = 210°$
(2) $21^m \div 4 = 5°15'$ (remainder $1^m \times 15 = 15'$)
(3) $39^s \div 4 = 9'45''$ (remainder $3^s \times 15 = 45''$)
(4) $14^h21^m39^s = 215°24'45'' = 215°24'.8$ (to nearest $0'.1$).

To convert arc to time:

1. Divide the degrees by 15 to obtain hours, and multiply the remainder by four to obtain minutes of time.

2. Divide the minutes of arc by 15 to obtain minutes of time, and multiply the remainder by four to obtain seconds of time.

3. Divide the seconds of arc by 15 to obtain seconds of time.

4. Add hours, minutes, and seconds.

Example 2.—Convert $215°24'45''$ to time units.

Solution.—

(1) $215° \div 15 = 14^h20^m$ (remainder $5° \times 4 = 20^m$)
(2) $24' \div 15 = 1^m36^s$ (remainder $9' \times 4 = 36^s$)
(3) $45'' \div 15 = 3^s$
(4) $215°24'45'' = 14^h21^m39^s$

Example 3.—Convert $161°53'.7$ to time units.

Solution.—

(1) $161° \div 15 = 10^h44^m$ (remainder $11° \times 4 = 44^m$)
(2) $53'.7 \div 15 = 3^m34^s.8$ (remainder $8'.7 \times 4 = 34^s.8$)
(3) $161°53'.7 = 10^h47^m34^s.8 = 10^h47^m35^s$

The navigator should be able to make these solutions mentally, writing only the answer. As a check, the answer can be converted back to the original value. Solution can also be made by means of arc to time tables in the almanacs. In the *Nautical Almanac* the table, given near the back of the volume (app. F), is in two parts, permitting separate entries with degrees, minutes, and quarter minutes of arc. The table is arranged in this manner because the navigator is confronted with the problem of converting arc to time more often than the reverse.

Example 4.—Convert $334°18'22''$ to time units, using the *Nautical Almanac* arc to time conversion table.

Solution.—

$334° = 22^h16^m$
$18'.25 = 1^m13^s$
$334°18'22'' = 22^h17^m13^s$

The $22''$ are converted to the nearest quarter minute of arc for solution to the nearest second of time. Interpolation can be used if more precise results are required, since exact relationships are tabulated in the *Nautical Almanac* conversion table.

Example 5.—Convert 83°29′.6 to time units, using the *Nautical Almanac* arc to time conversion table.

Solution.—

$$\begin{aligned} 83° &= 5^h32^m \\ 29'.6 &= \quad 1^m58^s.4 \\ \hline 83°29'.6 &= 5^h33^m58^s.4 \end{aligned}$$

In this solution, $58^s.4$ was obtained by eye interpolation in the quarter-minute part of the table.

Example 6.—Convert $17^h09^m42^s$ to arc units, using the *Nautical Almanac* arc to time conversion table.

Solution.—

$$\begin{aligned} 17^h08^m &= 257° \\ 1^m42^s &= \quad 25'.5 \\ \hline 17^h09^m42^s &= 257°25'.5 \end{aligned}$$

A similar table appears near the back of the *Air Almanac* (app. G); however, quarter minutes of arc are not included.

Example 7.—Convert 334°47′.2 to time units, using the *Air Almanac* arc to time conversion table.

Solution.—

$$\begin{aligned} 334° &= 22^h16^m \\ 47'.2 &= \quad 3^m09^s \\ \hline 334°47'.2 &= 22^h19^m09^s \end{aligned}$$

Example 8.—Convert $15^h13^m18^s$ to time units, using the *Air Almanac* arc to time conversion table.

Solution.—

$$\begin{aligned} 15^h12^m &= 228° \\ 1^m18^s &= \quad 19'.5 \\ \hline 15^h13^m18^s &= 228°19'.5 \end{aligned}$$

Because the almanac conversion tables are exact relationships, interpolation in them can be carried to any degree of precision desired without introducing an error.

605. Time and longitude.—As indicated in the preceding article, time is a measure of rotation of the earth, and any given time interval can be represented by a corresponding angle through which the earth turns. Suppose the celestial reference point were directly over a certain reference of the earth. An hour later the earth would have turned through 15°, and the celestial reference would be directly over a meridian 15° farther west. Any difference of longitude is a measure of the angle through which the earth must rotate for the local time at the western meridian to become what it was at the eastern meridian before the rotation took place. Therefore, places to the eastward of an observer have *later* time, and those to the westward have *earlier* time, and the difference is exactly equal to the difference in longitude, expressed in time units. When a meridian other than the local meridian is used as the time reference, the difference in time of two places is equal to the difference of longitude of their time reference meridians.

606. The date line.—Since time becomes later toward the east, and earlier toward the west, time at the lower branch of one's meridian is 12 hours earlier or later depending upon the direction of reckoning. A traveler making a trip around the world gains or loses an entire day. To prevent the *date* from being in error, and to provide a starting place for each day, a **date line** is fixed by international agreement. This line coincides with the 180th meridian over most of its length. In crossing this line, one alters his date by one day. In effect, this changes his time 24 hours to compensate for the slow

change during a trip around the world. Therefore, it is applied in the opposite direction to the change of time. Thus, if a person is traveling *eastward* from east longitude to west longitude, time is becoming *later*, and when the date line is crossed, the date becomes one day *earlier*. That is, at any moment the date immediately to the *west* of the date line (east longitude) is one day *later* than the date immediately to the *east* of the line, except at GMT 1200, when the (mean time) date is the same all over the world. At any other time two dates occur, one boundary between dates being the date line, and the other being the midnight line along the lower branch of the meridian over which the mean sun is located. At GMT 1200 these two boundaries coincide. In the solution of problems, error can sometimes be avoided by converting local time to Greenwich time, and then converting this to local time on the opposite side of the date line. Examples are given in following articles.

607. Zone time.—At sea, as well as ashore, watches and clocks are normally set approximately to some form of **zone time** (**ZT**). At sea the *nearest* meridian exactly divisible by 15° is usually used as the **time meridian** or **zone meridian**. Thus, within a **time zone** extending 7°.5 on each side of each time meridian the time is the same, and time in consecutive zones differs by exactly one hour. The time is changed as convenient, usually at a whole hour, near the time of crossing the boundary between zones. Each time zone is identified by the number of times the longitude of its zone meridian is divisible by 15°, positive in west longitude and negative in east longitude. This number and its sign, called the **zone description** (**ZD**), is the number of whole *hours* that are added to or subtracted from the zone time to obtain **Greenwich mean time** (**GMT**), which is the zone time at the Greenwich (0°) meridian, and is sometimes called **Universal Time** (**UT**). The mean sun is the celestial reference point for zone time.

Example 1.—For an observer at long. 141°18′.4W the ZT is $6^h18^m24^s$.

Required.—(1) Zone description.

(2) GMT.

Solution.—(1) The nearest meridian exactly divisible by 15° is 135°W, into which 15° will go nine times. Since longitude is west, ZD is (+)9.

	ZT	$6^h18^m24^s$
	ZD	(+) 9
(2)	GMT	$15^h18^m24^s$

In converting GMT to ZT, a positive ZD is *subtracted*, and a negative one *added*, but its sign remains the same, being part of the description. The word "reversed" (rev.) is written to the right in the work form to indicate that the "reverse" process is to be performed.

Example 2.—The GMT is $15^h27^m09^s$.

Required.—(1) ZT at long. 156°24′.4W.

(2) ZT at 39°04′.8E.

Solution.—

(1)	GMT	$15^h27^m09^s$	
	ZD	(+)10	(rev.)
	ZT	$5^h27^m09^s$	

(2)	GMT	$15^h27^m09^s$	
	ZD	(−) 3	(rev.)
	ZT	$18^h27^m09^s$	

When time at one place is converted to that at another, the date should be watched carefully. If a sum exceeds 24 hours, subtract this amount and add one day. If 24 hours are added before a subtraction is made, the date at the place is one day *earlier*.

Example 3.—At long. 73°29′.2W the ZT is $21^h12^m53^s$ on May 14.

Required.—(1) GMT and date.

(2) ZT and date at long. 107°15′.7W.

Solution.—

	ZT	$21^h12^m53^s$	May 14
	ZD	(+) 5	
(1)	GMT	$2^h12^m53^s$	May 15
	ZD	(+) 7	(rev.)
(2)	ZT	$19^h12^m53^s$	May 14

The second part of this problem might have been solved by using the *difference* in zone description. Since the second place is two zones farther west, its time is two hours earlier. Problems involving zone times at various places generally involve nothing more than addition or subtraction of one small number, so solutions can generally be made mentally. However, when this forms part of a larger problem, or when a record of the solution is desired, the full solution should be recorded, including labels.

Example 4.—On November 30 the 1430 DR long. of a ship is 51°32′.4W. Ten hours later the DR long. is 53°07′.2W.

Required.—ZT and date of arrival at the second longitude.

Solution.—

ZT	1430	Nov. 30
ZD	(+) 3	
GMT	1730	Nov. 30
int.	10	
GMT	0330	Dec. 1
ZD	(+) 4	(rev.)
ZT	2330	Nov. 30

If a time zone boundary had not been crossed, there would have been no need to find GMT. It is particularly helpful to retain this step when the date line is crossed. This line is the *center* of a time zone, the western (east longitude) half being designated (−) 12, and the eastern (west longitude) half (+) 12.

Example 5.—On December 31 the 0800 DR long. of a ship is 177°23′.9E. Forty hours later the DR long. is 171°53′.9W.

Required.—ZT and date of arrival at the second longitude.

Solution.—

ZT	0800	Dec. 31
ZD	(−)12	
GMT	2000	Dec. 30
int.	40	
GMT	1200	Jan. 1
ZD	(+)11	(rev.)
ZT	0100	Jan. 1

Alternative solution

ZT	$31^d08^h00^m$	
ZD	(−) 12	
GMT	$30^d20^h00^m$	
int.	1^d16^h	
GMT	$1^d12^h00^m$	
ZD	(+) 11	(rev.)
ZT	$1^d01^h00^m$	

For certain communication purposes it is sometimes convenient to designate a time zone by a single letter. The system used is shown in table 36.

Use of time zones on land began in 1883, when railroads adopted four standard zones for the continental United States. The division of the United States into time zones was not officially adopted by Congress, however, until March 19, 1918, when a fifth zone was also established for Alaska. The system of time zones is now used almost universally throughout the world, although on land the zone boundaries are generally altered somewhat for convenience. In a few places, half-hour zones are used.

On land, normal zone time is usually called **standard time,** often with an adjective to indicate the zone, as **eastern standard time.** In some areas timepieces are *advanced* one or more hours during the summer to provide greater use of daylight. This "fast"

time is called **daylight saving time** in the United States, and **summer time** elsewhere. When time is one hour fast, the zone description is (algebraically) one *less* than normal. When daylight saving or summer time is specified, an advance of one hour is understood unless a greater number is indicated.

Example 6.—What is the standard time and date at Tokyo, long. 140° E, when the daylight saving time at Washington, long. 77°W, is 1600 on Oct. 5?

Solution.—

ZT		1600 Oct. 5
ZD	(+)	4
GMT		2000 Oct. 5
ZD	(−)	9 (rev.)
ZT		0500 Oct. 6

During hostilities daylight saving time may be kept all year long throughout a nation, and designated **war time.**

608. Chronometer time (C) is time indicated by a chronometer. Since a chronometer is set approximately to GMT, and not reset until it is overhauled and cleaned, perhaps three or more years later, there is nearly always a **chronometer error** (CE), either *fast* (F) or *slow* (S). The change in chronometer error in 24 hours is called **chronometer rate,** or **daily rate,** and designated *gaining* or *losing.* With a consistent rate of 1^s per day for three years, the chronometer error would be approximately 18^m. Since chronometer error is subject to change, it should be determined from time to time, preferably daily at sea. Chronometer error is found by radio time signal, by comparison with another timepiece of known error, or by applying chronometer rate to previous readings of the same instrument. It is recorded to the nearest whole or half second. Chronometer rate is recorded to the nearest $0^s.1$.

Example 1.—At GMT 1200 on May 12 the chronometer reads $12^h04^m21^s$. At GMT 1600 on May 18 it reads $4^h04^m25^s$.

Required.—(1) Chronometer error at both comparisons.

(2) Chronometer rate.

(3) Chronometer error at GMT 0530 on May 27.

Solution.—

	GMT	1200^m00^s May 12
	C	$12^h04^m21^s$
(1)	CE	(F) 4^m21^s

	GMT	$16^h00^m00^s$ May 18
	C	$4^h04^m25^s$
(1)	CE	(F) 4^m25^s

	GMT	12^d12^h
	GMT	18^d16^h
	diff.	$6^d04^h = 6^d.2$

	CE	(F) 4^m21^s 1200 May 12
	CE	(F) 4^m25^s 1600 May 18
	diff.	4^s gained
(2)	daily rate	$0^s.6$ per day, gaining. ($4^s \div 6^d.2$)

	GMT	$18^d16^h00^m$
	GMT	$27^d05^h30^m$
	diff.	$8^d13^h30^m = 8^d.5$

CE (F) 4^m25^s 1600 May 18
corr. (+)5^s ($8^d.5 \times 0^s.6$ per day)
(3) CE (F) 4^m30^s 0530 May 27

Because GMT is stated on a 24-hour basis, and chronometer time on a 12-hour basis, a 12-hour ambiguity exists. This is ignored in finding chronometer error. However, if chronometer error is applied to chronometer time to find GMT, a possible 12-hour error can result. This can be resolved by mentally applying zone description to local time to obtain approximate GMT. A time diagram can be used for resolving doubt as to approximate GMT and Greenwich date. If the sun for the kind of time used (mean or apparent) is between the *lower* branches of two time meridians (as the standard meridian for local time, and the Greenwich meridian for GMT), the date at the place farther *east* is one day *later* than at the place farther *west*.

Example 2.—On August 14 the DR long. of a ship is about 124°E, and the zone time is about 0500. Chronometer error is 12^m27^s slow.

Required.—GMT and date when the chronometer reads $8^h44^m22^s$.

Solution.—

approx. ZT 0500 Aug. 14
ZD (−) 8
approx. GMT 2100 Aug. 13

C $8^h44^m22^s$
CE (S)12^m27^s
GMT $20^h56^m49^s$ Aug. 13

The *A* chronometer, usually the best (having the most nearly uniform rate), is compared directly with the time signal. Other chronometers, designated *B*, *C*, etc., may then be compared with the *A* chronometer.

Example 3.—At GMT 1400 chronometer *A* is checked by time signal, and found to read $1^h57^m09^s$. A little later, when it reads $2^h05^m00^s$, chronometer *B* reads $2^h11^m38^s$.

Required.—(1) Error of chronometer *A*.
(2) Error of chronometer *B*.

Solution.—

GMT $14^h00^m00^s$
C_A $1^h57^m09^s$
(1) CE_A (S) 2^m51^s
C_A $2^h05^m00^s$
GMT $14^h07^m51^s$
C_B $2^h11^m38^s$
(2) CE_B (F) 3^m47^s

If time signals are not available at the chronometer, a good comparing watch should be compared with the radio signal, and this watch used to determine chronometer error, as indicated in example 3, substituting the watch for chronometer *A*.

609. Watch time (**WT**) is time indicated by a watch. This is usually an approximation of zone time, except that for timing celestial observations it is good practice to set a hack or comparing watch to GMT. If the watch has a second setting hand, the watch can be set exactly to ZT or GMT, and the time is so designated. If the watch is not set exactly to one of these times, the difference is known as **watch error** (**WE**), labeled *fast* (F) or *slow* (S) to indicate whether the watch is ahead of or behind the correct time, respectively.

If a watch is to be set exactly to ZT or GMT, it is set to some whole minute slightly ahead of the correct time, and stopped. When the set time arrives, the watch is started. It should then be checked for accuracy.

Example 1.—A chronometer 9^m46^s fast on GMT reads approximately 7^h23^m. At the next whole five minutes of GMT a comparing watch is to be set to GMT exactly.

Required.—(1) What should the watch read at the moment of starting?

(2) What should the chronometer read?

Solution.—

	C	$7^h23^m00^s$
	CE	(F) 9^m46^s
	GMT	$7^h13^m14^s$
(1)	GMT	$7^h15^m00^s$ (next whole 5^m)
	CE	(F) 9^m46^s
(2)	C	$7^h24^m46^s$

The GMT may be in error by 12^h, but if the watch is graduated to 12 hours, this will not be reflected. If a watch with a 24-hour dial is used, the actual GMT should be determined.

If watch error is to be determined, it is done by comparing the reading of the watch with that of the chronometer at a selected moment. This may be at some selected GMT, as in example 1.

Example 2.—If, in example 1, the watch had read $7^h14^m48^s$ at the moment the chronometer read $7^h24^m46^s$, what would be the watch error on GMT?

Solution.—

GMT	$7^h15^m00^s$
WT	$7^h14^m48^s$
WE	(S) 12^s

A more convenient chronometer time might be selected, as a whole minute.

Example 3.—A watch is set to zone time approximately. The longitude is about 48°W. The watch is compared with a chronometer which is 19^m44^s fast on GMT. When the chronometer reads $5^h22^m00^s$, the watch reads $2^h01^m53^s$.

Required.—Watch error on zone time.

Solution.—

C		$5^h22^m00^s$	
CE		(F) 19^m44^s	
GMT		$5^h02^m16^s$	
ZD	(+)	3	(rev.)
ZT		$2^h02^m16^s$	
WT		$2^h01^m53^s$	
WE		(S) 23^s	

The possible 12^h error is not of significance. When such a watch is used for determining GMT, however, as for entering an almanac, the 12-hour ambiguity is important. Unless a watch is graduated to 24 hours, its time is designated AM before noon and PM after noon.

Example 4.—On January 3 the DR long. is 94°14′.7E. An observation of the sun is made when the watch reads $12^h16^m23^s$ PM. The watch is 22^s fast on zone time.

Required.—GMT and date.
Solution.—

WT		12^h16^m2[illegible] PM Jan. 3
WE		(F) [illegible]
ZT		$12^h16^m01^s$
ZD	(−)	6
GMT		$6^h16^m01^s$ Jan. 3

Note that between 1200 and 1300 watch designations are PM. Between 0000 and 0100 they are AM.

Comparison of a watch and chronometer should be made carefully. If two observers are available, one can give a warning "stand-by" a few seconds before the selected time, and a "mark" at the appointed moment, while the other notes the time of the watch. A single observer can make a satisfactory comparison by counting with the chronometer. Chronometers beat in half seconds, with an audible "tick." Ten seconds before the selected time (perhaps a whole minute), the observer starts counting with the beats, as he watches the chronometer second hand, "50, and, 1, and, 2, and, 3, and,. . . . . 9, and, mark." During the count the observer shifts his view from the chronometer to the second hand of the watch, continuing to count in cadence with the chronometer beats. At the "mark," the second, minute, and hour hands of the watch are read in that order, and the time recorded. A comparison of this time with the GMT or ZT corresponding to the selected chronometer time indicates the watch error.

Even though a watch is set to zone time approximately, its error on GMT can be determined and used for timing observations. In this case the 12-hour ambiguity in GMT should be resolved, and a time diagram used to avoid possible error. This method requires additional work, and presents a greater probability of error, without compensating advantages.

Still another method of determining GMT, generally used before zone time came into common use at sea, is to *subtract* watch time from chronometer time, to find C–WT. This is then *added* to the watch time of an observation to obtain chronometer time (C−WT+WT=C). Chronometer error is then applied to the result to obtain GMT. A time diagram should *always* be used with this method, to resolve the 12-hour ambiguity and to be sure of the correct Greenwich date, unless an auxiliary solution is made using approximate ZT and ZD. This method has little to recommend it.

If a watch has a **watch rate** of more than a few seconds per day, watch error should be determined both before and after a round of sights, and any difference distributed proportionally among observations.

If a stop watch is used for timing observations, it should be started at some convenient GMT, as a whole 5^m or 10^m. The time of each observation is then this GMT *plus* the reading of the watch.

610. Local mean time (LMT), like zone time, uses the mean sun as the celestial reference point. It differs from zone time in that the local meridian is used as the terrestrial reference, rather than a zone meridian. Thus, the local mean time at each meridian differs from that of every other meridian, the difference being equal to the difference of longitude, expressed in time units. At each zone meridian, including 0°, LMT and ZT are identical.

Example 1.—At long. 124°37′.2W the LMT is $17^h24^m18^s$ on March 21.
Required.—(1) GMT and date.
(2) ZT and date at the place.

Solution.—

LMT		$17^h24^m18^s$	Mar. 21
λ		$8^h18^m29^s$W	
(1) GMT		$1^h42^m47^s$	Mar. 22
ZD	(+)	8	(rev.)
(2) ZT		$17^h42^m47^s$	Mar. 21

In navigation the principal use of LMT is in rising, setting, and twilight tables. The problem is usually one of converting the LMT taken from the table to ZT. At sea, the difference between these times is normally not more than 30^m, and the conversion is made directly, without finding GMT as an intermediate step. This is done by applying a correction equal to the difference of longitude (dλ). If the observer is *west* of his time meridian, the correction is *added*, and if *east* of it, the correction is *subtracted*. If Greenwich time is desired, it is found from ZT.

Example 2.—At long. 63°24′.4E the LMT is 0525 on January 2.

Required.—(1) ZT and date.

(2) GMT and date.

Solution.—

LMT		0525	Jan. 2
dλ	(−)	14	
(1) ZT		0511	Jan. 2
ZD	(−)	4	
(2) GMT		0111	Jan. 2

On land, with an irregular zone boundary, the longitude may differ by more than 7°.5 (30^m) from the time meridian.

If LMT is to be corrected to daylight saving time, the difference in longitude between the local and time meridian can be used, or the ZT can first be found and then increased by one hour.

Conversion of ZT (including GMT) to LMT is the same as conversion in the opposite direction, except that the sign of dλ is reversed. This problem is not normally encountered in navigation.

611. Apparent time utilizes the **apparent** (real) **sun** as its celestial reference, and a meridian as the terrestrial reference. **Local apparent time** (**LAT**) uses the local meridian. The LAT at the 0° meridian is called **Greenwich apparent time** (**GAT**).

The LAT at one meridian differs from that at any other by the difference in longitude of the two places, the place to the eastward having the later time, and conversion is the same as converting LMT at one place to LMT at another.

Use of the apparent sun as a celestial reference point for time results in time of nonconstant rate for at least three reasons. First, revolution of the earth in its orbit is not constant. Second, motion of the apparent sun is along the ecliptic, which is tilted with respect to the celestial equator, along which time is measured. Third, rotation of the earth on its axis is not constant. The effect due by this third cause is extremely small.

For the various forms of mean time, the apparent sun is replaced by a fictitious **mean sun** conceived as moving eastward along the *celestial equator*, at a uniform speed equal to the average speed of the apparent sun along the ecliptic, thus providing a nearly uniform measure of time equal to the approximate average apparent time. At any moment the accumulated difference between LAT and LMT is indicated by the **equation of time** (**Eq. T**), which reaches a maximum value of about $16^m.4$ in November. This quantity is tabulated at 12-hour intervals at the bottom of the right-hand daily

page of the *Nautical Almanac*. In the United States, the sign is considered positive (+) if the time of sun's "Mer. Pass." is earlier than 1200, and negative (−) if later than 1200. If the "Mer. Pass." is given as 1200 (as on June 12–14, 1975), the sign is positive if the GHA at GMT 1200 is between 0° and 1°, and negative if it is greater than 359°. The sign is correct for conversion of GMT to GAT. In Great Britain, this convention is reversed. A heavy line is used to indicate a change of sign between consecutive entries, as shown between 00^h and 12^h on June 14, when the sign changes from positive to negative.

Example.—Find the LAT and date at ZT $15^h10^m40^s$ on May 31, 1975, for long. 73°18′.4W.

Solution.—

ZT		$15^h10^m40^s$ May 31
ZD	(+)	5
GMT		$20^h10^m40^s$ May 31
Eq. T		$(+)2^m25^s$
GAT		$20^h13^m05^s$ May 31
λ		$4^h53^m14^s$W
LAT		$15^h19^m51^s$ May 31

In conversion from apparent to mean time, a second solution may be needed if the equation of time is large and changing rapidly, using the GAT for entering the almanac for the first solution, and using the GMT from this solution as the almanac entry value for the second solution.

Apparent time can also be found by converting hour angle to time units, and adding or subtracting 12 hours. If LAT is required, but not GAT, conversion of arc to time should be made from LHA, rather than GHA, to avoid the need for conversion of longitude to time units. Equation of time can be found by *subtracting* mean time from apparent time at the same meridian. This method of finding apparent time and equation of time is the only one available with the *Air Almanac*, which does not tabulate equation of time.

The navigator has little or no use for apparent time, as such. However, it can be used for finding the time of **local apparent noon** (**LAN**), when the apparent sun is on the celestial meridian.

The mean sun averages out the irregularities in time due to the variations of the speed of revolution of the earth in its orbit and the fact that the apparent sun moves in the ecliptic while hour angle is measured along the celestial equator. It does not eliminate the error due to slight variations in the *rotational* speed of the earth. When a correction for the accumulated error from this source is applied to mean time, **ephemeris time** results. This time is of interest to astronomers, but is not used directly by the navigator.

612. Sidereal time uses the first point of Aries (vernal equinox) as the celestial reference point. Since the earth revolves around the sun, and since the direction of the earth's rotation and revolution are the same, it completes a rotation with respect to the stars in less time (about $3^m56^s.6$ of mean solar units) than with respect to the sun, and during one revolution about the sun (one year) it makes one complete rotation more with respect to the stars than with the sun. This accounts for the daily shift of the stars nearly 1° westward each night. Hence, sidereal days are shorter than solar days, and its hours, minutes, and seconds are correspondingly shorter. Because of nutation sidereal time is not quite constant in rate. Time based upon the average rate is called **mean sidereal time,** when it is to be distinguished from the slightly irregular sidereal time. The ratio of mean solar time units to mean sidereal time units is 1:1.00273791.

The sidereal *day* begins when the first point of Aries is over the *upper* branch of the meridian, and extends through 24 hours of sidereal time. The sun is at the first point of Aries at the time of the vernal equinox, about March 21. However, since the solar day begins when the sun is over the *lower* branch of the meridian, apparent solar and sidereal times differ by 12 hours at the vernal equinox. Each month thereafter, sidereal time *gains* about two hours on solar time. By the time of the summer solstice, about June 21, sidereal time is 18 hours *ahead* or six hours *behind* solar time. By the time of the autumnal equinox, about September 23, the two times are together, and by the time of the winter solstice, about December 22, the sidereal ime is six hours *ahead* of solar time. There need be no confusion of the date, for there is no sidereal date.

Local sidereal time (**LST**) uses the local meridan as the terrestrial reference. At the prime meridian this is called **Greenwich sidereal time** (**GST**). The difference between LST at two meridians is equal to the difference of longitude between them, the place to the eastward having the later time. Local sidereal time is LHA ♈ expressed in time units. To determine LST at any given moment, find GHA ♈ by means of an almanac, and then apply the longitude to convert it to LHA ♈. Then convert LHA ♈ in arc to LST in time units.

Example.—Find LST at ZT $8^h25^m51^s$ on May 31, 1975, for long. 103°16′.3E.

Solution.—

ZT	$8^h25^m51^s$ May 31
ZD	(−)7
GMT	$1^h25^m51^s$ May 31
1^h	262°54′.8
25^m51^s	6°28′.8
GHA ♈	269°23′.6
λ	103°16′.3E
LHA ♈	12°39′.9
LST	$0^h50^m40^s$

Unless GST is required, conversion from arc to time units should be made from LHA ♈, rather than from GHA ♈, to avoid the need for converting longitude from arc to time units.

Conversion of sidereal to solar time is the reverse. Local sidereal time is converted to arc (LHA ♈), and the longitude is applied to find GHA ♈. This is used as an argument for entering the almanac to determine GMT, which can then be converted to any other kind of time desired. This is similar to one method of finding time of meridian transit, described in article 733. Normally, the problem is not encountered by the navigator.

Sidereal time, as such, is little used by the navigator. It is the basis of star charts, star finders and identifiers, and certain sight reduction methods (Volume I of Pub. No. 249), but generally in the form LHA ♈. This kind of time is used for these purposes because its celestial reference point remains almost fixed in relation to the stars.

613. Time and hour angle.—Both time and hour angle are a measure of the phase of rotation of the earth, since both indicate the angular distance of a celestial reference point *west* of a terrestrial reference meridian. Hour angle, however, applies to *any* point on the celestial sphere. Time might be used in this respect, but only the apparent sun, mean sun, the first point of Aries, and occasionally the moon are commonly used.

Hour angles are usually expressed in arc units, and are measured from the upper branch of the celestial meridian. Time is customarily expressed in time units. Sidereal time is measured from the upper branch of the celestial meridian, like hour angle, but

solar time is measured from the lower branch. Thus, LMT=LHA mean sun plus or minus 180°, LAT=LHA apparent sun plus or minus 180°, and LST=LHA ♈.

As with time, **local hour angle** (**LHA**), based upon the local celestial meridian, at two places differs by the longitude between them, and LHA at longitude 0° is called **Greenwich hour angle** (**GHA**). In addition, it is often convenient to express hour angle in terms of the *shorter* arc between the local celestial meridian and the body. This is similar to measurement of longitude from the Greenwich meridian. Local hour angle measured in this way is called **meridian angle** (**t**), which is labeled *east* or *west*, like longitude, to indicate the direction of measurement. A westerly meridian angle is numerically equal to LHA, while an easterly meridian angle is equal to 360°−LHA; also, LHA=t (W), and LHA=360°−t (E). Meridian angle is used in the solution of the navigational triangle.

Example 1.—Find LHA and t of the sun at GMT $3^h24^m16^s$ on June 1, 1975, for long. 118°48′.2W.

Solution.—

GMT	$3^h24^m16^s$ June 1
3^h	225°35′.7
24^m16^s	6°04′.0
GHA	231°39′.7
λ	118°48′.2W
LHA	112°51′.5
t	112°51′.5W

Example 2.—Find LHA and t of Kochab at ZT $18^h24^m47^s$ on May 31, 1975, for long. 55°27′.3W.

Solution.—

	Kochab	
ZT	$18^h24^m47^s$	May 31
ZD	(+) 4	
GMT	$22^h24^m47^s$	May 31
22^h	218°46′.5	
24^m47^s	6°12′.8	
SHA	137°17′.7	
GHA	2°17′.0	
λ	55°27′.3W	
LHA	306°49′.7	
t	53°10′.3E	

Problems

603a. What is the time and date $9^h13^m29^s$ before $3^h16^m34^s$ May 9?

Answer.—T $18^h03^m05^s$ May 8.

603b. What is the time and date $4^d19^h22^m50^s$ after $9^h31^m04^s$ on December 25?

Answer.—T $4^h53^m54^s$ on Dec. 30.

603c. What is the time and date 2 years, 11 months, 16 days, 10 hours, 23 minutes, and 48 seconds before $2^h46^m17^s$ on October 4, 1958?

Answer.—T $16^h22^m29^s$ on Oct. 17, 1955.

603d. What is the time and date 412 days, 15 hours, 6 minutes, and 56 seconds after $22^h27^m03^s$ on March 16, 1958?

Answer.—T $13^h33^m59^s$ on May 3, 1959.

604a. Convert $6^h28^m31^s$ to arc units, without use of a conversion table.
Answer.—97°07′45″ or 97°07′.8.

604b. Convert 217°28′.8 to time units, without use of a conversion table.
Answer.—$14^h29^m55^s.2$ or $14^h29^m55^s$.

604c. Convert 196°21′46″ to time units, without use of a conversion table.
Answer.—$13^h05^m27^s.1$ or $13^h05^m27^s$.

604d. Convert 107°49′44″ to time units, using appendix F.
Answer.—$7^h11^m19^s$.

604e. Convert 211°37′.3 to time units, using appendix F.
Answer.—$14^h06^m29^s.2$.

604f. Convert $8^h49^m33^s$ to arc units, using appendix F.
Answer.—132°23′.2.

604g. Convert 251°09′.2 to time units, using appendix G.
Answer.—$16^h44^m37^s$.

604h. Convert $23^h07^m38^s$ to time units, using appendix G.
Answer.—346°54′.5.

607a. For an observer at long. 97°24′.6E the ZT is $19^h10^m26^s$.
Required.—(1) Zone description.
(2) GMT.
Answers.—(1) ZD (−) 6, (2) GMT $13^h10^m26^s$.

607b. The GMT is $11^h32^m07^s$.
Required.—(1) ZT at long. 133°24′.7W.
(2) ZT at long. 111°43′.9E.
Answers.—(1) ZT $2^h32^m07^s$, (2) ZT $18^h32^m07^s$.

607c. At long. 165°18′.2E the ZT is $17^h08^m51^s$ on July 11.
Required.—(1) GMT and date.
(2) ZT and date at long. 125°36′.7W.
Answers.—(1) GMT $6^h08^m51^s$ on July 11, (2) ZT $22^h08^m51^s$ on July 10.

607d. On January 26 the 0800 DR long. of a ship is 128°03′.2E. Twenty-six hours later the EP long. is 125°01′.4E.
Required.—ZT and date of arrival at the second longitude.
Answer.—ZT 0900 Jan. 27.

607e. On April 1 the 1200 running fix long. of a ship is 179°55′.2W. Eight hours later the DR long. is 178°48′.9E.
Required.—ZT and date of arrival at the second longitude.
Answer.—ZT 2000 Apr. 2.

607f. Inch'ŏn, long. 137°E, uses ZD (−) 8^h30^m for standard time. Find the standard time and date at San Francisco, long. 122°W, when the summer time at Inch'ŏn is 2000 on August 9.
Answer.—ZT 0230 Aug. 9.

608a. At GMT 1400 on July 2 the chronometer reads $1^h42^m28^s$. At GMT 0800 on July 12 it reads $7^h42^m40^s$.
Required.—(1) Chronometer error at GMT 1400 on July 2.
(2) Chronometer error at GMT 0800 on July 12.
(3) Chronometer rate.
(4) Chronometer time at ZT 1800 July 20, at long. 153°21′.7W.
Answers.—(1) CE 17^m32^s slow, (2) CE 17^m20^s slow, (3) rate $1^s.2$ gaining, (4) C $3^h42^m51^s$.

608b. On March 5 the DR long. of a ship is about 151°E, and the zone time is about 1800. Chronometer error is 6^m40^s fast.

Required.—GMT and date when the chronometer reads $8^h02^m23^s$.

Answer.—GMT $7^h55^m43^s$ on Mar. 5.

608c. On November 7 the EP long. of a ship is about 71°W, and the zone time is about 1900. Chronometer error is 1^m18^s slow.

Required.—GMT and date when the chronometer reads (1) $11^h55^m20^s$, (2) $11^h59^m50^s$.

Answers.—(1) GMT $23^h56^m38^s$ Nov. 7, (2) GMT $0^h01^m08^s$ Nov. 8.

608d. At GMT 2200 a comparing watch is checked by time signal, and found to read $10^h00^m05^s$. The chronometer errors are then determined by means of the comparing watch. When the watch reads $10^h06^m00^s$, chronometer *A* reads $10^h11^m17^s$, and when the watch reads $10^h08^m00^s$, chronometer *B* reads $9^h59^m06^s$.

Required.—(1) Watch error.

(2) Error of chronometer *A*.

(3) Error of chronometer *B*.

Answers.—(1) WE 5^s fast on GMT, (2) CE_A 5^m22^s fast, (3) CE_B 8^m49^s slow.

609a. A chronometer 7^m22^s slow on GMT reads approximately 3^h45^m. About two minutes later, when the GMT is a whole minute, a comparing watch will be set to GMT exactly.

Required.—(1) Reading of the watch at starting.

(2) Reading of the chronometer.

Answers.—(1) WT $3^h54^m00^s$, (2) C $3^h46^m38^s$.

609b. A chronometer 5^m10^s fast on GMT reads approximately 5^h50^m. About one minute later, when the GMT is a whole minute, a comparing watch with a 24-hour dial will be set to GMT exactly. The ZT is approximately 1145 and the long. 94°W.

Required.—(1) Reading of the watch at starting.

(2) Reading of the chronometer.

(3) Watch error if, instead of being set to GMT, the watch setting is unchanged and the watch reads $17^h45^m32^s$ at comparison.

Answers.—(1) WT $17^h46^m00^s$, (2) C $5^h51^m10^s$, (3) WE 28^s slow on GMT.

609c. A watch is set to zone time, approximately. The long. is about 160°E. The watch is compared with a chronometer which is 3^m16^s fast on GMT. When the chronometer reads $1^h48^m00^s$, the watch reads $12^h45^m02^s$.

Required.—Watch error on zone time.

Answer.—WE 18^s fast on ZT.

609d. On February 14 the DR long. is 63°46′1W. An observation of Dubhe is made when the watch reads $6^h07^m30^s$ PM. The watch is 11^s slow on zone time.

Required.—GMT and date.

Answer.—GMT $22^h07^m41^s$ Feb. 14.

609e. On December 11 a watch is set to zone time, approximately. The long. is 137°W. The chronometer is 3^m36^s fast on GMT. When the chronometer reads $4^h40^m00^s$, the watch reads $7^h36^m06^s$ PM.

Required.—(1) Watch error on GMT.

(2) GMT and date about 20 minutes later, when the watch reads $7^h55^m52^s$.

Answers.—(1) WE $2^h59^m42^s$ fast on GMT, (2) GMT $4^h56^m10^s$ Dec. 12.

609f. Shortly before taking morning sights on January 17 the navigator compares his watch with the chronometer. When the chronometer reads $2^h30^m00^s$, the watch reads $6^h13^m12^s$ AM. The chronometer is 17^m15^s fast on GMT. The long. is 118°W.

Required.—(1) C–WT.

(2) GMT and date a little later when Regulus is observed at WT $6^h28^m47^s$ AM.

Answers.—(1) C–WT $8^h16^m48^s$, (2) GMT $14^h28^m20^s$ Jan. 17.

610a. At long. 138°09′.3E the LMT is $0^h09^m57^s$ on April 23.
Required.—(1) GMT and date.
(2) ZT and date at the place.
Answers.—(1) GMT $14^h57^m20^s$ Apr. 22, (2) ZT $23^h57^m20^s$ Apr. 22.

610b. At long. 157°18′.4W the LMT is 1931 on June 29.
Required.—(1) ZT and date.
(2) GMT and date.
Answers.—(1) ZT 2000 June 29, (2) GMT 0600 June 30.

610c. At long. 99°35′.7W the daylight saving time is $21^h29^m45^s$ on August 31.
Required.—(1) Standard time and date.
(2) LMT and date.
Answers.—(1) Standard time $20^h29^m45^s$ Aug. 31, (2) LMT $20^h51^m22^s$ Aug. 31.

611a. Find the LAT and date at ZT $5^h26^m13^s$ on June 12, 1975, for long. 9°28′.1E.
Answer.—LAT $5^h04^m21^s$ June 12.

611b. At long. 77°15′.5W the LAT is 1500 on June 13, 1975.
Required.—(1) ZT.
(2) LMT.
Answers.—(1) ZT $15^h08^m56^s$, (2) LMT $14^h59^m54^s$.

611c. Using the *Air Almanac*, find (1) LAT at long. 117°55′W, and (2) the Eq. T, at ZT $20^h43^m09^s$ on June 1, 1975.
Answers.—(1) LAT $20^h53^m44^s$, (2) Eq. T (+) 2^m15^s.

612a. Find LST at ZT $19^h24^m26^s$ on June 1, 1975, for long. 87°51′.2E.
Answer.—LST $11^h53^m29^s$.

612b. Find the ZT at LST $21^h20^m07^s$ on May 31, 1975, for long. 54°21′.3W.
Answer.—ZT $4^h24^m40^s$.

CHAPTER VII

CALCULATIONS OF CELESTIAL NAVIGATION

Finding GHA and Declination

701. Use of the almanacs.—The time used as an entering argument in the almanacs is 12^h + Greenwich hour angle of the mean sun and is denoted by GMT. This scale may differ from the broadcast time signals by an amount which, if ignored, will introduce an error of up to 0′.2 in longitude determined from astronomical observations. The difference arises because the time argument depends on the variable rate of rotation of the earth while the broadcast time signals are now based on an atomic time-scale. Step adjustments of exactly one second are made to the time signals as required (primarily at 24^h on December 31 and June 30) so that the difference between the time signals and GMT, as used in the almanacs, may not exceed $0^s.9$. Those who require to reduce observations to a precision of better than 1^s must therefore obtain the correction to the time signals from coding in the signal, or from other sources. The correction may be applied to each of the times of observation. Alternatively, the longitude, when determined from astronomical observations, may be corrected by the corresponding amount shown in the following table:

Correction to time signals	Correction to longitude
$-0^s.7$ to $-0^s.9$	0′.2 to east
$-0^s.6$ to $-0^s.3$	0′.1 to east
$-0^s.2$ to $+0^s.2$	no correction
$+0^s.3$ to $+0^s.6$	0′.1 to west
$+0^s.7$ to $+0^s.9$	0′.2 to west

The main contents of the almanacs consist of data from which the Greenwich hour angle (GHA) and the declination (Dec.) of all the bodies used for navigation can be obtained for any instant of Greenwich mean time (GMT). The local hour angle (LHA) can then be obtained by means of the formula:

$$\text{LHA} = \text{GHA} \begin{matrix} - \text{ west} \\ + \text{ east} \end{matrix} \text{ longitude.}$$

For the sun, moon, and the four navigational planets, the GHA and declination are tabulated directly in the *Nautical Almanac* for each hour of GMT throughout the year; in the *Air Almanac*, the values are tabulated for each whole 10^m of GMT. For the stars the sidereal hour angle (SHA) is given, and the GHA is obtained from:

$$\text{GHA Star} = \text{GHA Aries} + \text{SHA Star.}$$

The SHA and declination of the stars change slowly and may be regarded as constant over periods of several days or even months if lesser accuracy is required. The SHA and declination of stars tabulated in the *Air Almanac* may be considered constant to a precision of 1′ for the period covered by each of the three volumes providing the data for a whole year. Should the *Air Almanac* be published in two volumes, the SHA

and declination of stars tabulated in each volume could be considered constant to a precision of 1′.5 to 2′, with most data being closer to the smaller value. GHA Aries, or the Greenwich hour angle of the first point of Aries (the vernal equinox), is tabulated for each hour of GMT in the *Nautical Almanac* and for each whole 10^m of GMT in the *Air Almanac*. Permanent tables give the appropriate increments to the tabulated values of GHA and declination for the minutes and seconds of GMT.

In the *Nautical Almanac*, the permanent table for increments also includes corrections for v, the difference between the actual change of GHA in one hour and a constant value used in the interpolation tables and d, the change in declination in one hour.

In the *Nautical Almanac*, v is always positive unless a negative sign (−) is given. This can occur only in the case of Venus. For the sun, the tabulated values of GHA have been adjusted to reduce to a minimum the error caused by treating v as negligible; there is no v tabulated for the sun.

No sign is given for tabulated values of d, which is positive if declination is increasing, and negative if it is decreasing. The sign of a v or d value is given also to the related correction.

In the *Air Almanac*, the tabular values of the GHA of the moon are adjusted so that use of an interpolation table based on a fixed rate of change gives rise to negligible error; no such adjustment is necessary for the sun and planets. The tabulated declination values, except for the sun, are those for the *middle* of the interval between the time indicated and the next *following* time for which a value is given, making interpolation unnecessary. Thus, it is always important to take out the GHA and declination for the tabular GMT immediately before the time of observation.

In the *Air Almanac*, GHA Aries and the GHA and declination of the sun are tabulated to a precision of 0′.1. If these values are extracted with the tabular precision, the "Interpolation of GHA" table on the inside front cover (and flap) should not be used; use the "Interpolation of GHA Sun" and "Interpolation of GHA Aries" tables, as appropriate. These tables for interpolation to a precision of 0′.1 just precede the Polaris Table.

The instructions in the explanation of each volume to ignore the decimal in smaller type when extracting GHA Aries and GHA and declination of the sun to a precision of 1′ instead of rounding-off in the normal way are intended for the air navigator.

702. Finding GHA and declination of the sun.—*Nautical Almanac*. Enter the daily-page table with the whole hour next preceding the given GMT, unless this time is itself a whole hour, and take out the tabulated GHA and declination. Record, also, the d value given at the bottom of the declination column. Next, enter the increments and corrections table for the number of minutes of GMT. If there are seconds, use the next *earlier* whole minute. On the line corresponding to the seconds of GMT take the value from the sun-planets column. Add this to the value of GHA from the daily page to find GHA at the given time. Next, enter the correction table for the same minute with the d value, and take out the correction. Give this the sign of the d value, and apply it to the declination from the daily page. The result is the declination at the given time.

Example 1.—Find the GHA and declination of the sun at GMT $18^h24^m37^s$ on June 1, 1975, using the *Nautical Almanac*.

Solution.—

	Sun	
GMT	$18^h24^m37^s$	June 1
18^h	90°34′.3	
24^m37^s	6°09′.3	
GHA	96°43′.6	

	Sun	
GMT	$18^h24^m37^s$	June 1
18^h	22°02′.5N	d (+)0′.3
d corr.	(+)0′.1	
Dec.	22°02′.6N	

The correction table for GHA of the sun is based upon a rate of change of 15° per hour, the average rate during a year. At most times the rate differs slightly from this. The slight error thus introduced is minimized by adjustment of the tabular values.

The *d* value is the amount that the declination changes between 1200 and 1300 on the middle day of the three shown.

Air Almanac. Enter the daily page with the whole 10^m next preceding the given GMT, unless the time is itself a whole 10^m, and extract the tabulated GHA. The declination is extracted, without interpolation, from the same line as the tabulated GHA or, in the case of planets, the top line of the block of six. If the values extracted are rounded to the nearest minute, next enter the "Interpolation of GHA" table on the inside front cover (and flap), using the "Sun, etc." entry column, and take out the value for the remaining minutes and seconds of GMT. If the entry time is an exact tabulated value, use the correction given half a line *above* the entry time. Add this correction to the GHA taken from the daily page to find the GHA at the given time. No adjustment of declination is needed. If the values are extracted with a precision of 0′.1, the table for interpolating the GHA of the sun to a precision of 0′.1 must be used. No adjustment of declination is needed.

Example 2.—Find the GHA and declination of the sun at GMT $18^h24^m37^s$ on June 1, 1975, using the *Air Almanac.*

Solution.—

	Sun	
GMT	$18^h24^m37^s$	June 1
18^h20^m	95°34′	
4^m37^s	1°09′	
GHA	96°43′	
Dec.	22°03′N	

	Sun	
GMT	$18^h24^m37^s$	June 1
18^h20^m	95°34′.3	
4^m37^s	1°09′.3	
GHA	96°43′.6	
Dec.	22°02′.6N	

703. Finding GHA and declination of the moon.—*Nautical Almanac.* Enter the daily-page table with the whole hour next preceding the given GMT, unless this time is itself a whole hour, and take out the tabulated GHA and declination. Record, also, the corresponding *v* and *d* values tabulated on the same line, and determine the sign of the *d* value. The *v* value of the moon is always positive (+), and is not marked in the almanac. Next, enter the increments and corrections table for the minutes of GMT, and on the line for the seconds of GMT take the GHA correction from the moon column. Then, enter the correction table for the same minute with the *v* value, and extract the correction. Add both of these corrections to the GHA from the daily page to obtain the GHA at the given time. Then, enter the same correction table with the *d* value, and extract the correction. Give this correction the sign of the *d* value, and apply it to the declination from the daily page to find the declination at the given time.

Example 1.—Find the GHA and declination of the moon at GMT $21^h25^m44^s$ on June 1, 1975, using the *Nautical Almanac.*

Solution.—

	Moon	
GMT	$21^h25^m44^s$	June 1
21^h	225°28′.1	
25^m44^s	6°08′.4	*v* (+)15′.8
v corr.	(+)6′.7	
GHA	231°43′.2	

	Moon	
GMT	$21^h25^m44^s$	June 1
21^h	3°06′.8S	*d* (−)10′.7
d corr.	(−)4′.5	
Dec.	3°02′.3S	

The correction table for GHA of the moon is based upon the *minimum* rate at which the moon's GHA increases, 14°19′.0 per hour. The *v* correction makes the ad-

justment for the actual rate. The v value itself is the difference between the minimum rate and the actual rate during the hour following the tabulated time. The d value is the amount that the declination changes during the hour following the tabulated time.

Air Almanac. Enter the daily page with the whole 10^m next preceding the given GMT, unless this time is itself a whole 10^m, and take out the tabulated GHA and the declination, without interpolation. Next, enter the "Interpolation of GHA" table on the inside front cover, using the "moon" entry column, and take out the value for the remaining minutes and seconds of GMT. If the entry time is an exact tabulated value, use the correction given half a line *above* the entry time. Add this correction to the GHA taken from the daily page to find the GHA at the given time. No adjustment of declination is needed.

Example 2.—Find the GHA and declination of the moon at GMT $21^h25^m44^s$ on June 1, 1975, using the *Air Almanac.*

Solution.—

	Moon	
GMT	$21^h25^m44^s$	June 1
21^h20^m	230°20′	
5^m44^s	1°23′	
GHA	231°43′	
Dec.	3°02′S	

The declination given in the table is correct for the time *five minutes later than tabulated*, so that it can be used for the ten-minute interval without interpolation, to an accuracy to meet most requirements. If greater accuracy is needed, it can be obtained by interpolation, remembering to allow for the five minutes indicated above.

704. Finding GHA and declination of a planet.—*Nautical Almanac.* Enter the daily-page table with the whole hour next preceding the given GMT, unless the time itself is a whole hour, and take out the tabulated GHA and declination. Record, also, the v value given at the bottom of each of these columns. Next, enter the increments and corrections table for the minutes of GMT, and on the line for the seconds of GMT take the GHA correction from the sun-planets column. Next, enter the correction table with the v value and extract the correction, giving it the sign of the v value. Add the first correction to the GHA from the daily page, and apply the second correction in accordance with its sign, to obtain the GHA at the given time. Then, enter the correction table for the same minute with the d value, and extract the correction. Give this correction the sign of the d value, and apply it to the declination from the daily page to find the declination at the given time.

Example 1.—Find the GHA and declination of Venus at GMT $5^h24^m07^s$ on June 2, 1975, using the *Nautical Almanac.*

Solution.—

	Venus	
GMT	$5^h24^m07^s$	June 2
5^h	206°59′.4	
24^m07^s	6°01′.8	v (−)0′.4
v corr.	(−)0′.2	
GHA	213°01′.0	

	Venus	
GMT	$5^h24^m07^s$	June 2
5^h	23°30′.8N	d (−)0′.5
d corr.	(−)0′.2	
Dec.	23°30′.6N	

The correction table for GHA of planets is based upon the mean rate of the sun, 15° per hour. The v value is the difference between 15° and the change of GHA of the planet between 1200 and 1300 on the middle day of the three shown. The d value is the amount that the declination changes between 1200 and 1300 on the middle day.

Venus is the only body listed which ever has a negative v value.

Air Almanac. Enter the daily page with the whole 10^m next preceding the given GMT, unless this time is itself a whole 10^m, and extract the tabulated GHA and declination, without interpolation. The tabulated declination is correct for the time 30^m later than tabulated, so that interpolation during the hour following tabulation is not needed for most purposes. Next, enter the "Interpolation of GHA" table on the inside front cover, using the "sun, etc." column, and take out the value for the remaining minutes and seconds of GMT. If the entry time is an exact tabulated value, use the correction half a line *above* the entry time. Add this correction to the GHA from the daily page to find the GHA at the given time. No adjustment of declination is needed.

Example 2.—Find the GHA and declination of Venus at GMT $5^h48^m45^s$ on June 2, 1975, using the *Air Almanac.*

Solution.—

	Venus
GMT	$5^h48^m45^s$ June 2
5^h40^m	216°59′
8^m45^s	2°11′
GHA	219°10′
Dec.	23°31′N

The declination is taken for the next *earlier* tabulated time, and is correct for GMT 5^h45^m.

705. Finding GHA and declination of a star.—If the GHA and declination of each navigational star were tabulated separately, the almanacs would be several times their present size. But since the sidereal hour angle (art. 501) and the declination are nearly constant over several days (to the nearest 0′.1) or months (to the nearest 1′), separate tabulations are not needed. Instead, the GHA of the first point of Aries, from which SHA is measured, is tabulated on the daily pages, and a single listing of SHA and declination is given for each double page of the *Nautical Almanac*, and for an entire volume of the *Air Almanac*. The finding of GHA ♈ is similar to finding GHA of the sun, moon, and planets.

Nautical Almanac. Enter the daily-page table with the whole hour next preceding the given GMT, unless this time is itself a whole hour, and take out the tabulated GHA ♈. Record, also, the tabulated SHA and declination of the star from the listing on the left-hand daily page. Next, enter the increments and corrections table for the minutes of GMT, and on the line for the seconds of GMT take the GHA correction from the Aries column. Add this correction and the SHA of the star to the GHA ♈ of the daily page to find the GHA of the star at the given time. No adjustment of declination is needed.

Example 1.—Find the GHA and declination of Canopus at GMT $3^h24^m33^s$ on June 2, 1975, using the *Nautical Almanac.*

Solution.—

	Canopus
GMT	$3^h24^m33^s$ June 2
3^h	294°58′.0
24^m33^s	6°09′.3
SHA	264°09′.3
GHA	205°16′.6
Dec.	52°41′.1S

The SHA and declination of 173 stars, including Polaris and the 57 listed on the daily pages, are given for the middle of each month, on almanac pages 268–273. For a star not listed on the daily pages this is the only almanac source of this information. Interpolation in this table is not necessary for ordinary purposes of navigation, but is sometimes needed for precise results. Thus, if the SHA and declination of *β Crucis* (Mimosa) are desired for March 1, 1975, they are found by simple eye interpolation to be SHA 168°25′.2 and Dec. 59°33′.2S.

If GHA ♈ is desired, it is found as indicated in example 1, but omitting the addition of SHA of a star. In the example GHA ♈ is 294°58′.0+6°09′.3=301°07′.3.

Air Almanac. Enter the daily page with the whole 10^m next preceding the given GMT, unless this is itself a whole 10^m, and extract the tabulated GHA ♈. Next, enter the "Interpolation of GHA" table on the inside front cover, using the "sun, etc." entry column, and take out the value for the remaining minutes and seconds of GMT. If the entry time is an exact tabulated value, use the correction given half a line *above* the entry time. From the tabulation at the left side of the same page, extract the SHA and declination of the star. Add the GHA from the daily page and the two values taken from the inside front cover to find the GHA at the given time. No adjustment of declination is needed.

Example 2.—Find the GHA and declination of Peacock at GMT $12^h17^m58^s$ on June 1, 1975, using the *Air Almanac.*

Solution.—

	Peacock
GMT	$12^h17^m58^s$ June 1
12^h10^m	71°52′
7^m58^s	2°00′
SHA	54°03′
GHA	127°55′
Dec.	56°49′S

The Undivided Astronomical Triangle

706. Solving for altitude.—The law of cosines for sides is a fundamental formula for solving a spherical triangle. As applied to the spherical triangle of figure 706a, the law is stated as:

$$\cos a = \cos b \cos c + \sin b \sin c \cos A \quad (1a)$$
$$\cos b = \cos c \cos a + \sin c \sin a \cos B \quad (1b)$$
$$\cos c = \cos a \cos b + \sin a \sin b \cos C. \quad (1c)$$

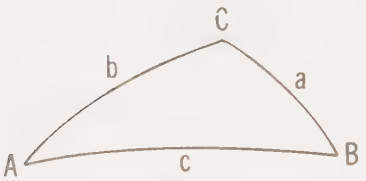

FIGURE 706a.—Spherical triangle.

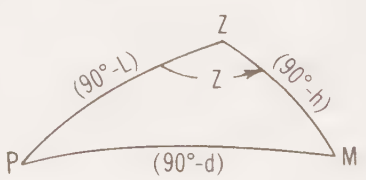

FIGURE 706b.—Undivided astronomical triangle.

As applied to the undivided astronomical triangle of figure 706b, equation 1a is stated as:

$$\cos(90°-h) = \cos(90°-L)\cos(90°-d)+\sin(90°-L)\sin(90°-d)\cos LHA$$
$$\therefore \sin h = \sin L \sin d + \cos L \cos d \cos LHA, \quad (2a)$$

in which h is the altitude of the celestial body above the celestial horizon, L is the latitude of the observer or the assumed position of the observer, d is the declination of the body, and LHA is the local hour angle of the body. Meridian angle, t, can be substituted for LHA in the equation, i.e.,

$$\sin h = \sin L \sin d + \cos L \cos d \cos t. \tag{2b}$$

For both same and contrary name cases, the sine and cosine functions of latitude are positive. In the contrary name case, declination is considered as a negative angle. In this case the sine function of declination is negative and the cosine function is positive.

For both same and contrary name cases, the cosine function of the local hour angle is positive when it is in the range 0° increasing to 90°, or 270° increasing to 360°, i.e., the cosine function of the angle is positive when the LHA corresponds to a meridian angle of 90° or less. When the LHA is in the range greater than 90° and increasing to 270°, the cosine function of the angle is negative, i.e., the cosine function of LHA is negative when LHA corresponds to a meridian angle greater than 90°.

The rules for the following cases can also be used in the solution of equations 2a and 2b:

Case I ($t<90°$ and Same Name).

If LHA is in the range 0° increasing to 90°, or 270° increasing to 360° and the latitude is same name as declination, the two terms on the right-hand side of the equation are added. The body is above the celestial horizon.

Case II ($t<90°$ and Contrary Name).

If LHA is in the range 0° increasing to 90°, or 270° increasing to 360° and the latitude is of contrary name, the lesser quantity is subtracted from the greater on the right-hand side of the equation. The body can be above or below the celestial horizon.

Case III ($t>90°$ and Same Name).

If LHA is in the range greater than 90° and increasing to 270° and the latitude is same name as declination, the lesser quantity is subtracted from the greater on the right-hand side of the equation. The body can be above or below the celestial horizon.

Case IV ($t>90°$ and Contrary Name).

If LHA is in the range greater than 90° and increasing to 270° and the latitude is of contrary name, the two quantities on the right-hand side of the equation are added. The body is below the celestial horizon.

Astronomical triangles corresponding to the four cases are drawn on diagrams on the plane of the celestial meridian in figure 706c.

Example 1.—The latitude of the observer is 45°00′.0N; the declination of the celestial body is 5°00′.0N; the local hour angle is 60°.

Required.—Altitude of the body.

Solution.—By natural functions (table 31).

$$\begin{aligned}
\sin h &= \sin L \sin d + \cos L \cos d \cos LHA \qquad (2a)\\
&= \sin 45° \sin 5° + \cos 45° \cos 5° \cos 60°\\
&= (+0.70711)(+0.08716) + (+0.70711)(+0.99619)(+0.50000)\\
&= +0.06163 + 0.35221 \qquad \text{(Case I)}\\
&= +0.41384\\
h &= 24°26′.8
\end{aligned}$$

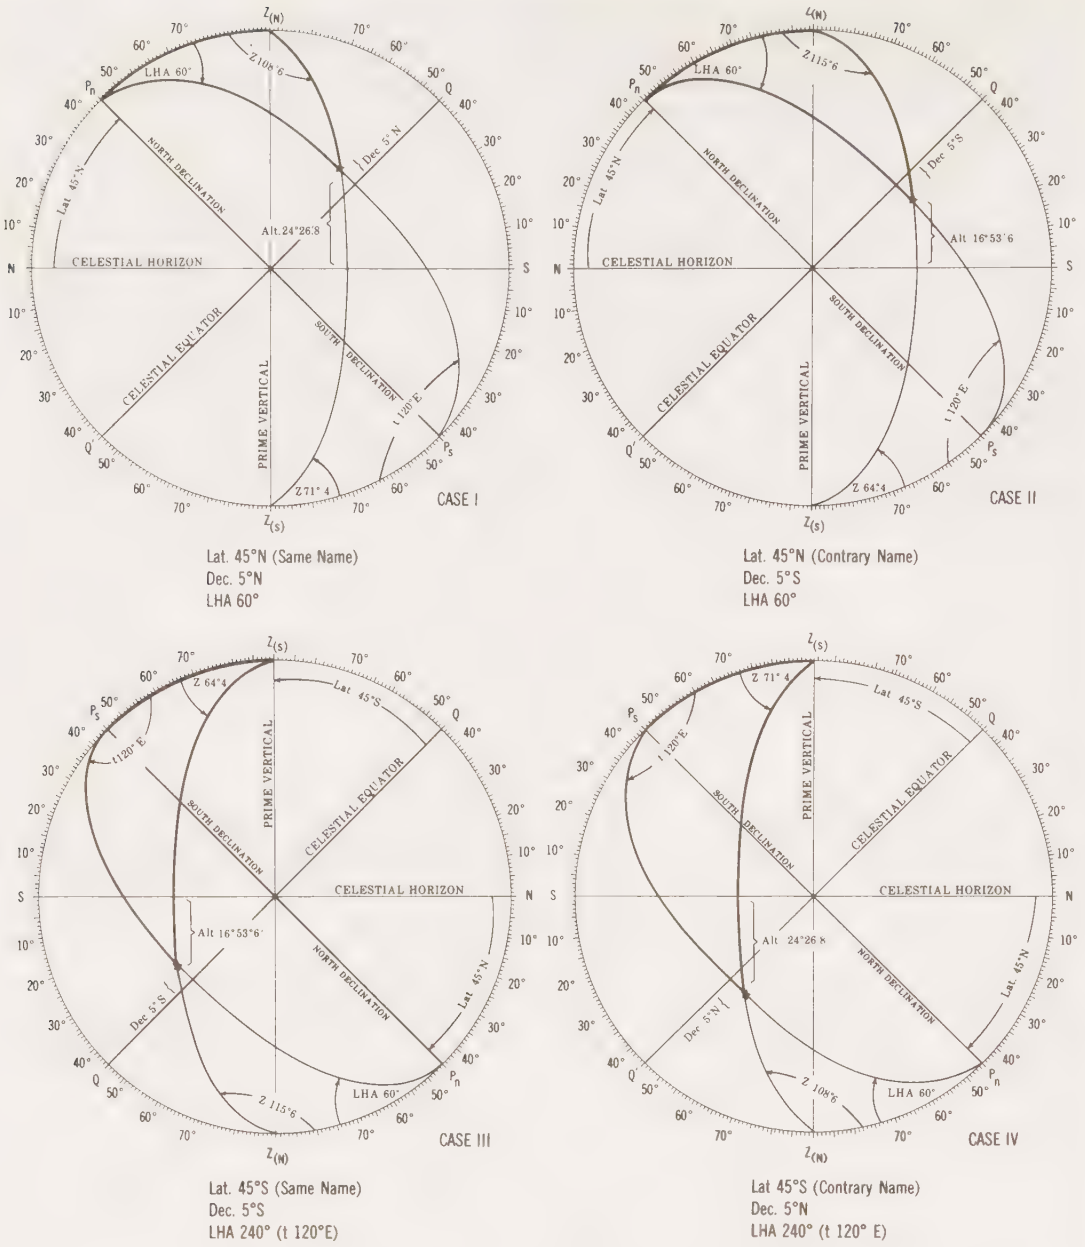

FIGURE 706c.—Diagrams on the plane of the celestial meridian.

Example 2.—The latitude of the observer is 45°00′.0N; the declination of the celestial body is 5°00′.0S; the local hour angle is 60°.

Required.—Altitude of the body.

Solution.—By natural functions (table 31).

$$\sin h = \sin L \sin d + \cos L \cos d \cos LHA \qquad (2a)$$

$$= \sin 45° \sin -5° + \cos 45° \cos -5° \cos 60°$$

$$= (+0.70711)(-0.08716) + (+0.70711)(+0.99619)(+0.50000)$$

$$= -0.06163 + 0.35221 \qquad \text{(Case II)}$$

$$= +0.29058$$

$$h = 16°53′.6$$

Example 3.—The latitude of the observer is 45°00′.0S; the declination of the celestial body is 5°00′.0S; the local hour angle is 240°.

Required.—Altitude of the body.

Solution.—By natural functions (table 31).

$$\begin{aligned}\sin h &= \sin L \sin d + \cos L \cos d \cos LHA \qquad (2a)\\ &= \sin 45^\circ \sin 5^\circ + \cos 45^\circ \cos 5^\circ \cos 240^\circ\\ &= (+0.70711)(+0.08716) + (+0.70711)(+0.99619)(-0.50000)\\ &= +0.06163 - 0.35221 \qquad \text{(Case III)}\\ &= -0.29058\\ h &= -16^\circ 53'.6\end{aligned}$$

Example 4.—The latitude of the observer is 45°00′.0S; the declination of the celestial body is 5°00′.0N; the local hour angle is 240°.

Required.—Altitude of the body.

Solution.—By natural functions (table 31).

$$\begin{aligned}\sin h &= \sin L \sin d + \cos L \cos d \cos LHA \qquad (2a)\\ &= \sin 45^\circ \sin -5^\circ + \cos 45^\circ \cos -5^\circ \cos 240^\circ\\ &= (+0.70711)(-0.08716) + (+0.70711)(+0.99619)(-0.50000)\\ &= -0.06163 - 0.35221 \qquad \text{(Case IV)}\\ &= -0.41384\\ h &= -24^\circ 26'.8\end{aligned}$$

Example 5.—The latitude of the observer is 30°25′.0N; the declination of the celestial body is 22°06′.2N; the meridian angle is 39°54′.7W.

Required.—Altitude of the body.

Solution.—By natural and logarithmic functions (tables 31–33).

$$\begin{aligned}\sin h &= \sin L \sin d + \cos L \cos d \cos t \qquad (2b)\\ &= \sin 30^\circ 25'.0 \sin 22^\circ 06'.2 + \cos 30^\circ 25'.0 \cos 22^\circ 06'.2 \cos 39^\circ 54'.7\\ &= (0.50628)\ (0.37628) + (0.86237)\ (0.92651)\ (0.76703)\\ &= +0.19050 + 0.61285 \qquad \text{(Case I)}\\ &= +0.80335\\ h &= 53^\circ 27'.1\end{aligned}$$

For logarithmic solution by tables 32 and 33, the following modification is used:

$$\begin{aligned}A &= \sin L \sin d \qquad B = \cos L \cos d \cos t\\ \sin h &= A + B\\ \log A &= l \sin 30^\circ 25'.0 + l \sin 22^\circ 06'.2\\ \log B &= l \cos 30^\circ 25'.0 + l \cos 22^\circ 06'.2 + l \cos 39^\circ 54'.7\\ \log A &= 9.70439 + 9.57551 \qquad \log B = 9.93569 + 9.96685 + 9.88481\\ &= 9.27990 \qquad\qquad = 9.78735\\ A &= 0.19050 \text{ (table 32)} \qquad B = 0.61284 \text{ (table 32)}\\ \sin h &= A + B\\ &= 0.19050 + 0.61284 \qquad \text{(Case I)}\\ &= 0.80334\\ h &= 53^\circ 27'.0\end{aligned}$$

Example 6.—The latitude of the observer is 30°25′.0N; the declination of the celestial body is 22°06′.2S; the meridian angle is 39°54′.7W.

Required.—Altitude of the body.

Solution.—By natural and logarithmic functions (tables 31–33).

$$\begin{aligned}\sin h &= \sin L \sin d + \cos L \cos d \cos t \qquad (2b)\\ &= \sin 30°25'.0 \sin -22°06'.2 + \cos 30°25'.0 \cos -22°06'.2 \cos 39°54'.7\\ &= (0.50628)\ (-0.37628) + (0.86237)\ (0.92651)\ (0.76703)\\ &= -0.19050 + 0.61285 \quad \text{(Case II)}\\ &= +0.42235\\ h &= 24°59'.0\end{aligned}$$

For logarithmic solution by tables 32 and 33,

$$\begin{aligned}&A = \sin L \sin d \qquad B = \cos L \cos d \cos t\\ &\sin h = A \sim B\\ &\log A = l \sin 30°25'.0 + l \sin 22°06'.2,\\ &\log B = l \cos 30°25'.0 + l \cos 22°06'.2 + l \cos 39°54'.7\\ &\log A = 9.70439 + 9.57551 \qquad \log B = 9.93569 + 9.96685 + 9.88481\\ &\quad = 9.27990 \qquad\qquad\quad = 9.78735\\ &A = 0.19050 \text{ (table 32)} \qquad B = 0.61284 \text{ (table 32)}\\ &\sin h = A \sim B\\ &\quad = -0.19050 + 0.61284 \quad \text{(Case II)}\\ &\quad = +0.42234\\ &h = 24°59'.0\end{aligned}$$

Example 7.—The latitude of the observer is 30°25′.0S; the declination of the celestial body is 22°06′.2S; the meridian angle is 91°20′.0W.

Required.—Altitude of the body.

Solution.—By natural and logarithmic functions (tables 31–33).

$$\begin{aligned}\sin h &= \sin L \sin d + \cos L \cos d \cos t \qquad (2b)\\ &= \sin 30°25'.0 \sin 22°06'.2 + \cos 30°25'.0 \cos 22°06'.2 \cos 91°20'.0\\ &= (0.50628)(0.37628) + (0.86237)(0.92651)(-0.02327)\\ &= +0.19050 - 0.01859 \quad \text{(Case III)}\\ &= +0.17191\\ h &= 9°53'.9\end{aligned}$$

For logarithmic solution by tables 32 and 33,

$$\begin{aligned}&A = \sin L \sin d \qquad B = \cos L \cos d \cos t\\ &\sin h = A \sim B\\ &\log A = l \sin 30°25'.0 + l \sin 22°06'.2\\ &\log B = l \cos 30°25'.0 + l \cos 22°06'.2 + l \cos 91°20'.0\\ &\log A = 9.70439 + 9.57551 \qquad \log B = 9.93569 + 9.96685 + 8.36678\\ &\quad = 9.27990 \qquad\qquad\quad = 8.26932\\ &A = 0.19050 \text{ (table 32)} \qquad B = 0.01859 \text{ (table 32)}\\ &\sin h = A \sim B\\ &\quad = 0.19050 - 0.01859 \quad \text{(Case III)}\\ &\quad = 0.17191\\ &h = 9°53'.9\end{aligned}$$

Example 8.—The latitude of the observer is 30°25′.0S; the declination of the celestial body is 22°06′.2N; the meridian angle is 91°20′.0W.

Required.—Altitude of the body.

Solution.—By natural and logarithmic functions (tables 31–33).

$$\begin{aligned}\sin h &= \sin L \sin d + \cos L \cos d \cos t \qquad (2b)\\ &= \sin 30°25'.0 \sin -22°06'.2 + \cos 30°25'.0 \cos -22°06'.2 \cos 91°20'.0\\ &= (0.50628)\ (-0.37628) + (0.86237)\ (0.92651)\ (-0.02327)\\ &= -0.19050 - 0.01859 \quad \text{(Case IV)}\\ &= -0.20909\\ h &= -12°04'.1\end{aligned}$$

For logarithmic solution by tables 32 and 33,

$$\begin{aligned}&A = \sin L \sin d \qquad B = \cos L \cos d \cos t\\ &\sin h = A + B\\ &\log A = l \sin 30°25'.0 + l \sin 22°06'.2\\ &\log B = l \cos 30°25'.0 + l \cos 22°06'.2 + l \cos 91°20'.0\\ &\log A = 9.70439 + 9.57551 \qquad \log B = 9.93569 + 9.96685 + 8.36678\\ &\quad = 9.27990 \qquad\qquad = 8.26932\\ &A = 0.19050 \text{ (table 32)} \qquad B = 0.01859 \text{ (table 32)}\\ &\sin h = A + B\\ &\quad = 0.19050 + 0.01859 \quad \text{(Case IV)}\\ &\quad = 0.20909\\ &h = -12°04'.1\end{aligned}$$

Note: When the meridian angle is greater than 90° and the latitude and declination are of contrary name, the body lies below the celestial horizon.

707. Solving for azimuth.—The relations between the parts of a spherical triangle as shown in figure 707a are given in the following equations known as the **five parts formulas:**

$$\sin a \cos B = \cos b \sin c - \sin b \cos c \cos A \qquad (3a)$$
$$\sin b \cos C = \cos c \sin a - \sin c \cos a \cos B \qquad (3b)$$
$$\sin c \cos A = \cos a \sin b - \sin a \cos b \cos C. \qquad (3c)$$

Also by the law of sines:

$$\frac{\sin a}{\sin A} = \frac{\sin b}{\sin B} = \frac{\sin c}{\sin C}.$$

Substituting the value of sin a as obtained from the law of sines in equation 3a:

$$\sin a = \frac{\sin A \sin b}{\sin B}$$
$$\sin A \cot B = \sin c \cot b - \cos c \cos A.$$

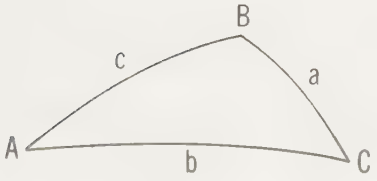

FIGURE 707a.—Spherical triangle.

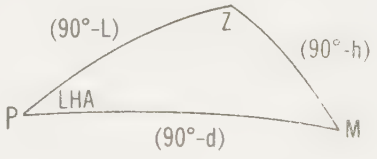

FIGURE 707b.—Undivided astronomical triangle.

As applied to the undivided astronomical triangle of figure 707b, the above equation is stated as:

$$\sin \text{LHA} \cot Z = \cos L \tan d - \sin L \cos \text{LHA}$$

from which

$$\cot Z = \frac{\cos L \tan d - \sin L \cos \text{LHA}}{\sin \text{LHA}}$$

$$\tan Z = \frac{\sin \text{LHA}}{\cos L \tan d - \sin L \cos \text{LHA}}.$$

Substituting $\frac{\sin d}{\cos d}$ for tan d,

$$\tan Z = \frac{\cos d \sin \text{LHA}}{\cos L \sin d - \sin L \cos d \cos \text{LHA}}. \tag{4}$$

Meridian angle, t, can be substituted for LHA in equation 4:

$$\tan Z = \frac{\cos d \sin t}{\cos L \sin d - \sin L \cos d \cos t}. \tag{5}$$

The sign rules as given for equations 2a and 2b are applicable. In addition, the sine function of LHA is positive when LHA is less than 180° and negative when LHA is greater than 180°. If LHA is less than 180° and the computed value of tan Z is negative, subtract the acute angle corresponding to this function from 180° to determine the value of the azimuth angle; if tan Z is positive, the acute angle is the azimuth angle. If LHA is greater than 180° and the computed value of tan Z is positive, subtract the acute angle corresponding to this function from 180° to determine the value of the azimuth angle; if tan Z is negative, the acute angle is the azimuth angle.

Azimuth angle is measured from 0° at the north or south reference direction clockwise or counter-clockwise through 180°. It is labeled with the reference direction as the prefix and the direction of measurement from the reference direction as a suffix. Thus, azimuth angle S144°W is 144° west of south, or true azimuth 324°. Azimuth angle is labeled N or S to agree with the latitude and E or W to agree with the meridian angle (labeled E when LHA is greater than 180°).

Azimuth angle can also be converted to true azimuth, Zn, through use of the following rules:

N. Lat.	LHA greater than 180°	Zn=Z
	LHA less than 180°	Zn=360°−Z
S. Lat.	LHA greater than 180°	Zn=180°−Z
	LHA less than 180°	Zn=180°+Z.

708. Time azimuth.—The time azimuth or azimuth angle is computed using the LHA or meridian angle (a function of time), latitude, and declination as the known quantities. Solution can be made using equations 4 or 5.

Example 1.—The latitude of the observer is 30°25′.0N; the declination of the celestial body is 22°06′.2N; the meridian angle is 39°54′.7W.

Required.—Azimuth of the body.

Solution.—By equation 5.

$$\tan Z=\frac{\cos d \sin t}{\cos L \sin d-\sin L \cos d \cos t} \tag{5}$$

$$=\frac{\cos 22°06'.2 \sin 39°54'.7}{\cos 30°25'.0 \sin 22°06'.2-\sin 30°25'.0 \cos 22°06'.2 \cos 39°54'.7}$$

$$=\frac{(+0.92651)(+0.64161)}{(+0.86237)(+0.37628)-(+0.50628)(+0.92651)(+0.76703)}$$

$$\tan Z=\frac{0.59446}{0.32449-0.35979}=\frac{0.59446}{-0.03530}=-16.84023.$$

Since the LHA is less than 180° and the computed value of tan Z is negative, the acute angle (86°.6) corresponding to the function is subtracted from 180° to obtain the azimuth angle:

$$Z=180°-86°.6=N93°.4W$$
$$Zn=266°.6.$$

Example 2.—The latitude of the observer is 30°25'.0S; the declination of the celestial body is 22°06'.2N; the meridian angle is 39°54'.7W.

Required.—Azimuth of the body.

Solution.—By equation 5.

$$\tan Z=\frac{\cos d \sin t}{\cos L \sin d-\sin L \cos d \cos t} \tag{5}$$

$$=\frac{\cos -22°06'.2 \sin 39°54'.7}{\cos 30°25'.0 \sin -22°06'.2-\sin 30°25'.0 \cos -22°06'.2 \cos 39°54'.7}$$

$$=\frac{(+0.92651)(+0.64161)}{(+0.86237)(-0.37628)-(+0.50628)(+0.92651)(+0.76703)}$$

$$\tan Z=\frac{+0.59446}{-0.32449-0.35979}=\frac{+0.59446}{-0.68428}=-0.86874.$$

Since the LHA is less than 180° and the computed value of tan Z is negative, the acute angle (41°.0) corresponding to the function is subtracted from 180° to obtain the azimuth angle:

$$Z=180°-41°.0=S139°.0W$$
$$Zn=319°.0.$$

709. Altitude azimuth.—The altitude azimuth is the azimuth or azimuth angle computed using altitude, latitude, and declination (or polar distance) as the known quantities.

By the law of cosines for sides,

$$\cos b=\cos c \cos a+\sin c \sin a \cos B. \tag{1b}$$

As applied to the astronomical triangle of figure 707b, equation 1b is stated as:

$$\cos(90°-d)=\cos(90°-L) \cos(90°-h)+\sin(90°-L) \sin(90°-h)\cos Z$$
$$\sin d=\sin L \sin h+\cos L \cos h \cos Z$$
$$\cos Z=\frac{\sin d-\sin L \sin h}{\cos L \cos h}. \tag{6}$$

Example.—The latitude of the observer is 30°00′.0N; the center of the sun is on the visible horizon; the declination of the sun is 18°00′.0N.

Required.—Azimuth angle of the sun.

Solution.—By equation 6.

Computation for azimuth angle is made for an altitude of (−)0°41′.4, determined as follows:

Dip at 41 feet height of eye	(−)	6′.2
Refraction at (−)6′.2 altitude	(−)	35′.3
Parallax	(+)	0′.1
	(−)	41′.4

$$\cos Z=\frac{\sin d-\sin L \sin h}{\cos L \cos h}=\frac{\sin 18°-\sin 30° \sin (-)0°41′.4}{\cos 30° \cos (-)0°41′.4} \tag{6}$$

$$=\frac{(0.30902)-(0.50000)(-0.01204)}{(0.86603)(0.99993)}=\frac{+0.31504}{+0.86597}=+0.36380$$

$$Z=68°40′.0.$$

710. Time and altitude azimuth.—The time and altitude azimuth or azimuth angle is computed using meridian angle, declination, and altitude as the known quantities. The most common formula is derived from the law of sines.

By the law of sines, the relationship between the angles and sides opposite of the spherical triangle shown in figure 706a is:

$$\frac{\sin b}{\sin B}=\frac{\sin a}{\sin A} \tag{3d}$$

As applied to the astronomical triangle of figure 707b, equation 3d is stated as:

$$\frac{\sin (90°-d)}{\sin Z}=\frac{\sin (90°-h)}{\sin t}$$

$$\sin Z \cos h=\sin t \cos d$$

$$\sin Z=\sin t \cos d \sec h. \tag{7}$$

The weakness of this method is that it does not indicate whether the celestial body is north or south of the prime vertical. Usually there is no question on this point, but if Z is near 90°, the quadrant may be in doubt. If this occurs, the meridian angle or altitude when on the prime vertical can be determined from table 25 (for declinations less than 23°) or by computation (art. 721), using the formula:

$$\cos t=\tan d \cot L \tag{14c}$$

or

$$\sin h=\sin d \csc L. \tag{14d}$$

Example.—The latitude of the observer is 30°25′.0N; the declination of the celestial body is 22°06′.2N; the altitude of the body is 53°27′.0; and the meridian angle is 39°54′.7W.

Required.—Azimuth of the body.

Solution.—By equation 7.

$$\sin Z=\sin t \cos d \sec h \tag{7}$$

$$=\sin 39°54′.7 \cos 22°06′.2 \sec 53°27′.0$$

$$=(+0.64161)(+0.92651)(+1.67919)$$

$$=0.99821$$

$$Z=86°.6 \text{ or } 93°.4 \text{ ?}$$

By logarithmic solution,

$$\begin{aligned} l \sin Z &= l \sin t + l \cos d + l \sec h \\ &= l \sin 39°54'.7 + l \cos 22°06'.2 + l \sec 53°27'.0 \\ &= 9.80726 + 9.96685 + 10.22510 \\ &= 9.99921 \\ Z &= 86°.6 \text{ or } 93°.4 \ ? \end{aligned}$$

If the altitude is *less*, or the meridian angle is *greater* than the value when the body is on the prime vertical, the numerical value of the azimuth angle is the lesser of the two angles. If the altitude is *greater* or the meridian angle is less when on the prime vertical, the numerical value of the azimuth angle is the greater of the two angles.

Entering table 25 with latitude 30°25′ and declination 22°06′.2 (same name as latitude) as arguments, the meridian angle and altitude of the body when on the prime vertical are determined as:

$$t = 46°.1, \qquad h = 48°.1.$$

Since the altitude is greater than the value when the body is on the prime vertical, the numerical value of the azimuth angle is the greater of the two quantities, i.e., the azimuth angle is N93°.4W; Zn is 266°.6.

711. Haversine formulas.—In the foregoing altitude and azimuth angle solutions, it has been necessary to consider the signs of the various trigonometric functions. This inconvenience can be avoided through the use of natural and log haversine functions, as given in table 34, because the haversine of an angle is positive whether the angle is positive or negative. The value increases from 0° to 180° and decreases from 180° to 360°. Since by convention only angles and sides up to 180° are considered, ambiguities are avoided.

By definition,

$$\text{haversine } A = \text{hav } A = \frac{1}{2} \text{ ver } A = \frac{1}{2}(1 - \cos A) = \sin^2 \frac{1}{2} A$$

and

$$\text{haversine } a = \text{hav } a = \frac{1}{2} \text{ ver } a = \frac{1}{2}(1 - \cos a) = \sin^2 \frac{1}{2} a.$$

Substituting $\cos A = 1 - 2 \text{ hav } A$ and $\cos a = 1 - 2 \text{ hav } a$ in the fundamental cosine formula:

$$\cos a = \cos b \cos c + \sin b \sin c \cos A \tag{1a}$$

$$\begin{aligned} 1 - 2 \text{ hav } a &= \cos b \cos c + \sin b \sin c (1 - 2 \text{ hav } A) \\ &= \cos b \cos c + \sin b \sin c - 2 \sin b \sin c \text{ hav } A. \end{aligned}$$

Since $\cos b \cos c + \sin b \sin c = \cos (b - c)$ and $\cos (b - c) = 1 - 2 \text{ hav } (b - c)$,

$$\begin{aligned} 1 - 2 \text{ hav } a &= 1 - 2 \text{ hav } (b - c) - 2 \sin b \sin c \text{ hav } A \\ \text{hav } a &= \text{hav } (b - c) + \sin b \sin c \text{ hav } A. \end{aligned}$$

Since the haversine is always positive, the value of hav(b − c) is positive irrespective of the values assigned to b and c. Therefore, (b − c) may be simplified by writing it as (b∼c), the difference of b and c. Thus,

$$\text{hav } a = \text{hav}(b \sim c) + \sin b \sin c \text{ hav } A. \tag{8a}$$

Similarly, it can be shown that:

$$\begin{aligned} \text{hav } b &= \text{hav}(a \sim c) + \sin a \sin c \text{ hav } B \\ \text{hav } c &= \text{hav}(a \sim b) + \sin a \sin b \text{ hav } C. \end{aligned}$$

712. Altitude by cosine-haversine formula.—The haversine formula for altitude as derived from the fundamental cosine formula is known as the cosine-haversine formula.

Substituting the parts of the astronomical triangle of figure 707b in equation 8a, side a is the zenith distance; side b is the polar distance; side c is the colatitude; and angle A is the meridian angle, t.

$$\text{hav a}=\text{hav (b}\sim\text{c)}+\sin \text{b} \sin \text{c hav A} \tag{8a}$$

$$\text{hav z}=\text{hav [(90°}-\text{d)}\sim\text{(90°}-\text{L)]}+\sin \text{(90°}-\text{d)} \sin \text{(90°}-\text{L) hav t}$$

$$\text{hav z}=\text{hav (L}\sim\text{d)}+\cos \text{d} \cos \text{L hav t.} \tag{8b}$$

Equation 8b is sometimes written

$$\text{hav z}=\text{hav (L}\sim\text{d)}+\text{hav } \theta, \tag{8c}$$

in which hav θ = cos d cos L hav t.

Equation 8b can also be written entirely in haversines:

$$\text{hav z}=\text{hav (d}-\text{L)}+\text{hav t [hav (180°}-\text{L}-\text{d)}-\text{hav (d}-\text{L)]}. \tag{8d}$$

In equation 8d the sign of d is reversed if L and d are of contrary name.

Example.—The latitude of the observer is 30°25′.0S; the declination of the celestial body is 22°06′.2N; and the meridian angle is 91°20′.0W.

Required.—Altitude of the body.

Solution.—By equation 8c and tables 33 and 34.

t	91°20′.0 W	*l* hav	9.70896		
L	30°25′.0 S	*l* cos	9.93569		
d	22°06′.2 N	*l* cos	9.96685		
θ		*l* hav	9.61150	*n* hav	0.40879
L∼d	52°31′.2			*n* hav	0.19575
z	102°04′.1			*n* hav	0.60454
h	−12°04′.1				

713. Azimuth by haversines.—The haversine formulas as transposed for convenience in the solutions of the three angles are known as the **cosecant formulas.**

$$\text{hav A}=[\text{hav a}-\text{hav(b}\sim\text{c)}] \csc \text{b} \csc \text{c} \tag{9a}$$

$$\text{hav B}=[\text{hav b}-\text{hav(a}\sim\text{c)}] \csc \text{a} \csc \text{c} \tag{9b}$$

$$\text{hav C}=[\text{hav c}-\text{hav(a}\sim\text{b)}] \csc \text{a} \csc \text{b.} \tag{9c}$$

As applied to the astronomical triangle of figure 707b, B is the azimuth angle; side a is the coaltitude; side b is the polar distance; and side c is the colatitude. Equation 9b is rewritten as:

$$\text{hav Z}=[\text{hav p}-\text{hav(z}\sim\text{coL)}] \csc \text{z} \csc \text{coL.} \tag{9d}$$

Another haversine formula for azimuth angle is derived from the following formula of trigonometry:

$$\sin^2 \frac{1}{2} \text{B}=\frac{\sin \text{(s}-\text{c)} \sin \text{(s}-\text{a)}}{\sin \text{c} \sin \text{a}},$$

in which s is one-half the sum of the three sides of the spherical triangle. As applied to the astronomical triangle of figure 707b, B is the azimuth angle Z; side a is the coaltitude; side b is the polar distance; and side c is the colatitude.

Thus, $$s=\frac{\text{coaltitude}+\text{polar distance}+\text{colatitude}}{2}$$

$$s=\frac{(90°-h)+p+(90°-L)}{2}=90°-\left(\frac{h+L-p}{2}\right)$$

$$s-c=90°-\left[\frac{h+L-p}{2}\right]-(90°-L)=\frac{p-(h-L)}{2}$$

$$s-a=90°-\left[\frac{h+L-p}{2}\right]-(90°-h)=\frac{p+(h-L)}{2}$$

Substituting in the basic equation,

$$\sin^2\frac{1}{2}Z=\text{hav } Z=\sin\left[\frac{p-(h-L)}{2}\right]\sin\left[\frac{p+(h-L)}{2}\right]\sec L\sec h. \tag{10a}$$

The formula for azimuth angle can also be stated as:

$$\text{hav } Z=\sin(S-L)\sin(S-h)\sec h\sec L, \tag{10b}$$

in which $S=\frac{1}{2}(h+L+p)$ and $S-h=\frac{1}{2}(L+p-h)$.

714. Altitude azimuth by haversines.—The altitude azimuth solution can be made by equation 10b:

$$\text{hav } Z=\sin(S-L)\sin(S-h)\sec h\sec L, \tag{10b}$$

in which

$$S=\frac{1}{2}(h+L+p).$$

Example.—The latitude of the observer is 30°25′.0N; the declination of the celestial body is 22°06′.2N (polar distance 67°53′.8); the altitude of the body is 53°27′.0.

Required.—Azimuth of the body.

Solution.—By equation 10b.

$$S=\frac{1}{2}(h+L+p)$$

$$=\frac{1}{2}(53°27'.0+30°25'.0+67°53'.8)=75°52'.9.$$

$$\text{hav } Z=\sin(S-L)\sin(S-h)\sec h\sec L \tag{10b}$$

$$=\sin(75°52'.9-30°25'.0)\sin(75°52'.9-53°27'.0)\sec 53°27'.0\sec 30°25'.0$$

$$=\sin 45°27'.9\sin 22°25'.9\sec 53°27'.0\sec 30°25'.0$$

$$=(+0.71282)(+0.38158)(+1.67919)(+1.15960)$$

$$=+0.52963$$

$Z=93°.4$ (table 34).

715. Solving for meridian angle.—The problem consists of finding the meridian angle from given values of altitude, latitude, and polar distance. Of the three elements, altitude, latitude, and declination used in the solution of the astronomical triangle, normally the only uncertain element is the latitude. Results are most accurate when the body is on or near the prime vertical, as then an error in latitude has least effect.

The haversine formula for meridian angle is derived from the following formula of trigonometry:

$$\sin^2\frac{1}{2}A=\frac{\sin(s-b)\sin(s-c)}{\sin b\sin c},$$

in which s is one-half of the sum of the three sides of the spherical triangle. As applied to the astronomical triangle of figure 707b, A is the meridian angle, t; side a is the coaltitude; side b is the polar distance; side c is the colatitude. Thus,

$$s=\frac{\text{coaltitude}+\text{polar distance}+\text{colatitude}}{2}$$

$$=\frac{(90°-h)+p+(90°-L)}{2}=90°-\left(\frac{h+L-p}{2}\right)$$

$$s-b=\left[90°-\left(\frac{h+L-p}{2}\right)-p\right]=90°-\left(\frac{h+L+p}{2}\right)$$

$$s-c=\left[90°-\left(\frac{h+L-p}{2}\right)-(90°-L)\right]=\frac{L+p-h}{2}.$$

Substituting in the basic equation,

$$\sin^2\frac{1}{2}t=\text{hav } t=\frac{\sin\left[90°-\left(\frac{h+L+p}{2}\right)\right]\sin\left(\frac{L+p-h}{2}\right)}{\sin p\cos L}. \tag{10c}$$

The formula for meridian angle can also be stated as:

$$\text{hav } t=\csc p\sec L\cos S\sin(S-h), \tag{10d}$$

in which $S=\frac{1}{2}(h+L+p)$ and $S-h=\frac{1}{2}(L+p-h)$.

The meridian angle of a body when its center is on the celestial horizon can be computed by the formula:

$$\cos t=\frac{1}{}-\tan L\tan d \tag{10e}$$

where t is the meridian angle, L is the latitude, and d is the declination. Solutions of this formula are given in table 25, if the table is entered with a latitude 90° from the given latitude. This table can be used for this purpose only when latitude and declination are of contrary name.

In deriving equation 10e by Napier's Rules of Circular Parts, the two sides of the spherical triangle forming the right angle are latitude and coamplitude (fig. 720b).

Example 1.—The latitude of the observer is 40°00′.0N; the declination of the sun is 21°57′.9N.

Required.—Meridian angle of sun at sunrise.

Solution.—By equation 10d and table 34.

Allowing 16′ for semidiameter and 34′ for refraction, the center of the sun is 50′ below the celestial horizon when the upper limb of the sun is just visible from sea level.

$$S=\frac{1}{2}(h+L+p)=\frac{1}{2}(-0°50′.0+40°00′.0+68°02′.1)=53°36′.0.$$

$$S-h=53°36′.0-(-0°50′.0)=54°26′.0.$$

Substituting in equation 10d,

$$\text{hav } t = \csc p \sec L \cos S \sin (S-h) \tag{10d}$$

$$l \text{ hav } t = l \csc 68°02'.1 + l \sec 40°00'.0 + l \cos 53°36'.0 + l \sin 54°26'.0$$
$$= 10.03273 + 10.11575 + 9.77336 + 9.91033$$
$$= 9.83217$$
$$t = 111°02'.1\text{E.}$$

Example 2.—The latitude of the observer on the Greenwich meridian is 40°00'.0N; at sunrise, the meridian angle of the sun is 111°02'.1E.

Required.—The LMT of sunrise.

Solution.—The solution is the reverse of finding GHA. The largest tabulated value of GHA in the almanac that does not exceed the desired GHA is found in the tabulation for the day, and recorded with its time. The difference between this value and the desired GHA is then used to enter the "Increments and Corrections" table. The time interval corresponding to this value is added to the time taken from the daily page.

t(G)	111°02'.1E
GHA	248°57'.9
4^h	240°35'.6
33^m29^s	8°22'.3
GMT	$4^h33^m29^s$
LMT	$4^h33^m29^s$*

Alternatively, the solution is effected using the Equation of Time. The meridian angle is converted to local apparent time (LAT); the Equation of Time is applied to LAT to find LMT.

t(G)	111°02'.1E
LAT	$4^h35^m52^s$
Eq. T	(+) 2^m20^s (rev.)
LMT	$4^h33^m32^s$*

*Because of the variations in refraction and height of eye, computation to a greater precision than 1^m is not justified.

716. Solving for parallactic angle.—An approximate value of the parallactic angle, X, accurate enough for most navigational requirements, can be calculated from the formula

$$\cos X = \frac{\Delta h}{60'}, \text{ where } \Delta h \tag{10f}$$

is the change in altitude for 60′ change in declination, local hour angle and latitude remaining constant.

Example.—The latitude of the observer is 30°00'.0N; the declination of the celestial body is 45°00'.0S; the local hour angle is 30°00'.0, and Δh as extracted from a sight reduction table is 53'.9.

Required.—The parallactic angle.

Solution.—By the approximate formula:

$$\cos X = \frac{\Delta h}{60'} = \frac{53'.9}{60'} = 0.89833$$

$$X = 26°04'.$$

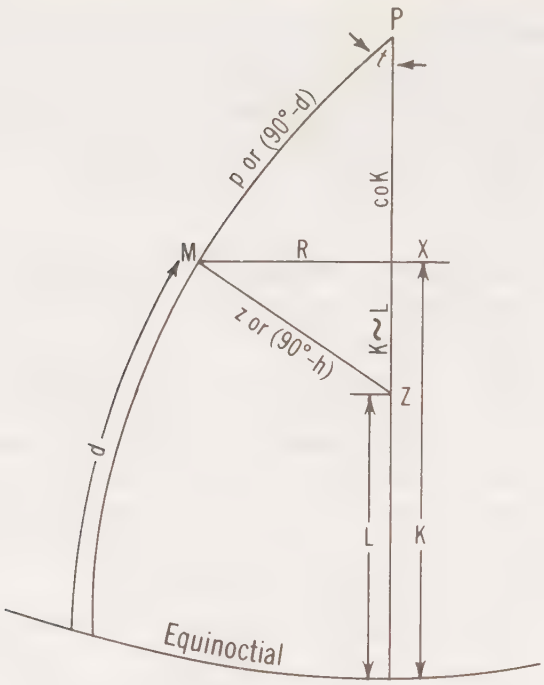

FIGURE 717a.—Divided astronomical triangle.

The Divided Astronomical Triangle

717. Development of the formulas.—In the divided astronomical triangle shown in figure 717a, the perpendicular is let fall from the celestial body to the celestial meridian. The parts of the triangle and special constructions are labeled as follows:

P, elevated pole of observer.
Z, zenith of observer or zenith of the assumed position of the observer.
M, celestial body.
L, latitude of observer or assumed position of observer.
d, declination of celestial body.
p, polar distance of celestial body.
t, meridian angle of celestial body.
h, altitude of celestial body.
R, perpendicular let fall from M on PZ. This is an auxiliary part.
X, intersection of R with PZ.
K, arc from X to celestial equator (equinoctial). This is an auxiliary part introduced to facilitate solution.

With the construction of auxiliary part R, the solutions of the unknown parts of the triangle can be effected through the solutions of right spherical triangles, using Napier's Rules of Circular Parts.

Omitting the right angle of the right spherical triangle of figure 717b, the triangle has five parts: two angles and three sides. The two sides forming the right angle and the *complements* of the other three parts are arranged in five sectors of the circular parts diagram in figure 717c in the same order in which they occur in the triangle of figure 717b.

Considering any part as the middle part, the two parts nearest it in the diagram are considered the *adjacent* parts, and the two farthest from it the *opposite* parts.

The rules are the sine of a middle part always equals the product of:

(1) the tangents of the adjacent parts or,

(2) the cosines of the opposite parts.

In the use of these rules the co-function of a complement is given as the function of the element. Thus, the cosine of co-A is the sine of A; the tangent of co-A is the cotangent of A, etc.

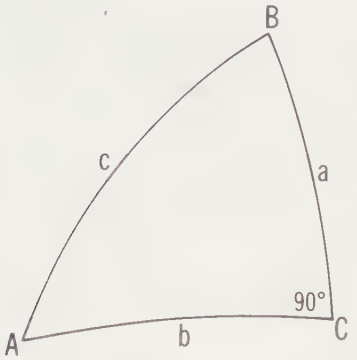

FIGURE 717b.—Right spherical triangle.

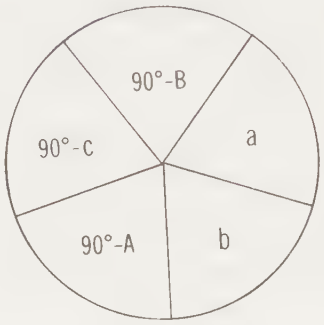

FIGURE 717c.—Circular parts diagram.

$$\sin a = \tan b \cot B = \sin c \sin A. \tag{11a}$$
$$\sin b = \tan a \cot A = \sin c \sin B. \tag{11b}$$
$$\cos c = \cot A \cot B = \cos a \cos b. \tag{11c}$$
$$\cos A = \tan b \cot c = \cos a \sin B. \tag{11d}$$
$$\cos B = \tan a \cot c = \cos b \sin A. \tag{11e}$$

Side c (the hypotenuse) is less than 90° when sides a and b are in the same quadrant, and more than 90° when a and b are in different quadrants. An oblique angle and the side opposite are in the same quadrant.

In applying Napier's rules to the right spherical triangle PMX of figure 717a, the five sectors of the circle are first completed as in figure 717d.

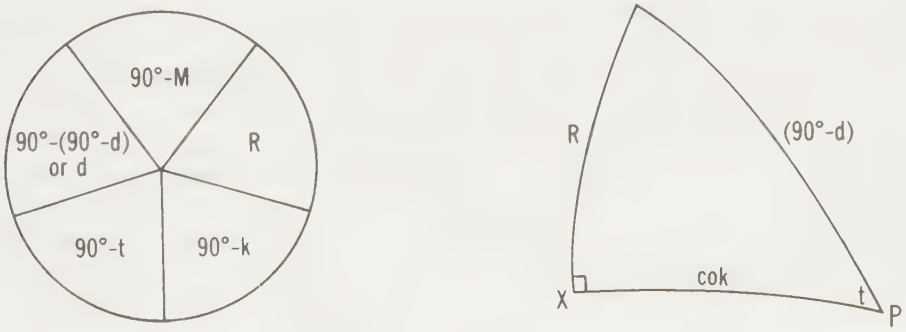

FIGURE 717d.—Circular parts diagram and triangle PMX.

$$\sin R = \cos (90° - t) \cos d$$
$$\sin R = \sin t \cos d$$
$$\csc R = \csc t \sec d. \tag{12a}$$

$$\sin d = \cos (90° - K) \cos R$$
$$\sin d = \sin K \cos R$$
$$\csc K = \csc d \div \sec R. \qquad (12b)$$

For right spherical triangle ZMX of figure 717a, the five sectors of the circle are completed as in figure 717e.

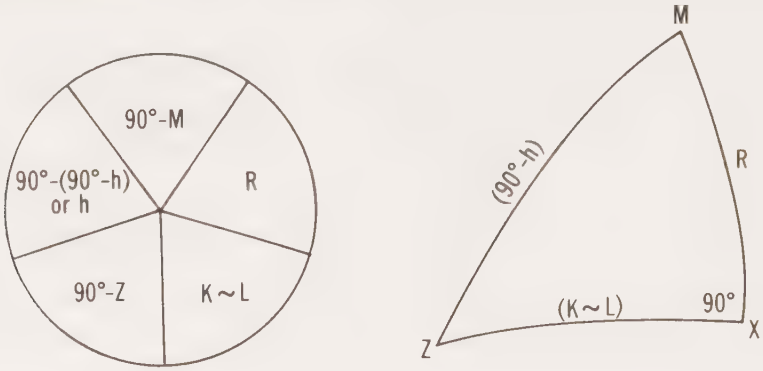

FIGURE 717e.—Circular parts diagram and triangle ZMX.

$$\sin h = \cos R \cos (K \sim L)$$
$$\csc h = \sec R \sec (K \sim L). \qquad (12c)$$

$$\sin R = \cos (90° - Z) \cos h$$
$$\sin R = \sin Z \cos h$$
$$\csc Z = \csc R \div \sec h. \qquad (12d)$$

With t and (90°—d) of triangle PMX known, part R is found by means of equation 12a. Knowing R and d, one can then find K by means of equation 12b. K is then combined algebraically with L to obtain (K∼L).

In triangle ZMX, sides R and (K∼L) are known. Equation 12c is used to obtain h. Azimuth angle, Z, is found by means of equation 12d.

718. The Ageton Method.—Table 35, The Ageton Method, can be used for the solution of the astronomical triangle divided by a perpendicular let fall from the celestial body to the celestial meridian. This table is arranged in parallel "A" and "B" columns, the "A" column containing log cosecants multiplied by 100,000 and the "B" column log secants multiplied by 100,000. This arrangement simplifies the arithmetic of solution of the formulas in terms of secants and cosecants. Ageton's ingenious arrangement of the calculations according to a standard form with simple, uniform rules also considerably simplifies the solution. The tabulation of functions every half of a minute throughout the tables aids interpolation.

Interpolation Requirements

For practical navigation, interpolation is normally required only when the quantity K or meridian angle, t, approaches 90°. When the quantity K is between 82° and 98°, it is good practice to either discard the sight or to interpolate the log secant (B) of R from the log cosecant (A) of R.

Solution by Table 35

The letters A and B indicate from which column of table 35 to take their corresponding functions.

The following steps are taken to obtain the altitude and azimuth angle in one combined solution using table 35:

1. Enter the table with meridian angle, t, and take from the A column the nearest tabulated number. Enter the table with declination and take the tabulated number from the B column. Add these numbers to obtain the A function of R.

2. Look up the number thus obtained in the A column and take from the B column the opposite tabulated number. Subtract this from the function of declination taken from the A column.

3. Enter the A column with the number thus obtained and take out the nearest tabulated value of K, the degrees from the top or bottom of the page and the minutes from the side.

4. Give K the same name as declination. Combine K with latitude to obtain (K∼L), adding K and latitude if of contrary name and subtracting the smaller from the larger if same name.

5. Enter the table with (K∼L) and take from the B column the nearest tabulated number. Add this to the B function of R.

6. With the number thus obtained, enter the A column and take h from the table.

7. To compute the azimuth angle look up h in the B column and subtract the number thus obtained from the A function of R, which has already been determined.

8. With this number, enter the A column and take out Z to the nearest minute. Z is always measured from the elevated pole 0° to 180° east or west to the body.

At the top of the pages of the table are stated the only two rules required.

(1) When Meridian Angle is Greater than 90°, Take K from Bottom of Table.

(2) Always Take "Z" from Bottom of Table, Except when K is Same Name and Greater than Latitude, in Which Case Take Z from Top of Table.

If a celestial body near the visible horizon is observed, it may be below the celestial horizon (zenith distance greater than 90°) because of refraction and dip. Under these conditions the altitude, h, is negative. In the solution by table 35, h is negative if K is of the same name as L and greater than (90°+L), or if K is of contrary name to L and greater than (90°−L). Under the second of these circumstances, Z is less than 90° and should be taken from the top of the table *if* K is greater than (180°−L).

When the azimuth angle is near 90°, the log cosecant (A) of Z may be a negative number if the tables have been used without interpolating. This can be avoided by interpolating throughout or by substituting the nearest tabulated value of A for the calculated value of log cosecant (A) of R at the top of the azimuth column.

"Wrinkles"

Certain short-cuts will become apparent with use of the table:

When entering the table with declination, take functions from both A and B columns in one entry.

When taking h from the table, take the tabulated function from the B column at the same time, as it will be used in computing Z.

Example 1.—The latitude of the observer is 42°10′.5S. The declination of a celestial body is 23°07′.0S; the meridian angle is 61°33′.8E.

Required.—Altitude and azimuth of the body.

Solution.—By table 35:

		Add	*Subtract*	*Add*	*Subtract*
t	61°33′.8E	A 5583			
d	23°07′.0S	B 3635	A 40604

Compass Error

719. Azimuth by tables.—One of the more frequent applications of sight reduction tables is their use in computing the azimuth of a celestial body for comparison with an observed azimuth in order to determine the error of the compass. In computing the azimuth of a celestial body, for the time and place of observation, it is normally necessary to interpolate the tabular azimuth angle as extracted from the tables for the differences between the table arguments and the actual values of declination, latitude, and local hour angle. The required triple interpolation of the azimuth angle using Pub. No. 229, *Sight Reduction Tables for Marine Navigation*, is effected as follows:

(1) Refer to figure 719a. The main tables are entered with the nearest integral values of declination, latitude, and local hour angle. For these arguments, a base azimuth angle is extracted.

(2) The tables are reentered with the same latitude and LHA arguments but with the declination argument 1° greater or less than the base declination argument depending upon whether the actual declination is greater or less than the base argument. The difference between the respondent azimuth angle and the base azimuth angle establishes the azimuth angle difference (Z Diff.) for the increment of declination.

(3) The tables are reentered with the base declination and LHA arguments but with the latitude argument 1° greater or less than the base latitude argument depending upon whether the actual (usually DR) latitude is greater or less than the base argument to find the Z Diff. for the increment of latitude.

(4) The tables are reentered with the base declination and latitude arguments but with the LHA argument 1° greater or less than the base LHA argument depending upon whether the actual LHA is greater or less than the base argument to find the Z Diff. for the increment of LHA.

(5) The correction to the base azimuth angle for each increment is Z Diff. $\times \frac{\text{Inc.}}{60'}$.

The auxiliary interpolation table (art. 206) can normally be used for computing this value because the successive azimuth angle differences are less than 10°.0 for altitudes less than 84°.

Example 1.—In DR lat. 33°24′.0N, the azimuth of the sun is observed as 096°.5 pgc. At the time of the observation, the declination of the sun is 20°13′.8N; the local hour angle of the sun is 316°41′.2.

Required.—The gyro error.

Solution.—By Pub. No. 229:

The error of the gyrocompass is found as shown in figure 719b.

FIGURE 719b.—Azimuth by Pub. No. 229.

Using Pub. No. 214, *Tables of Computed Altitude and Azimuth*, to determine the azimuth from the tabular values which are actually azimuth angles, interpolation is made for meridian angle, declination, and latitude.

Example 2.—In DR lat. 41°25′.9S, the azimuth of the sun is observed as 016°.0 pgc. At the time of the observation, the declination of the sun is 22°19′.6N; the meridian angle of the sun is 17°22′.4E.

Required.—The gyro error.

Solution.—By Pub. No. 214:

(1) Refer to appendix K. In this example the tabular azimuth angle used as base Z is compared with the tabular azimuth angle for the base declination and latitude, but meridian angle 18° to determine the Z Diff. for meridian angle. Similarly, the base Z is compared with the tabular value for the base meridian angle and latitude, but declination 22° to determine the Z Diff. for declination; and with the base value of meridian angle and declination, but latitude 42° to determine the Z Diff. for latitude.

(2) Interpolation is between whole degrees of meridian angle and latitude, but between half degrees of declination when the declination is 29° or less. For declinations of more than 29°, the interpolation interval for declination varies.

$$\text{t corr.} = \text{Z Diff.} \times \frac{\text{Increments}}{1^\circ} = (-)1^\circ.0 \times \frac{0^\circ.4}{1^\circ.0} = (-)0^\circ.4.$$

$$\text{d corr.} = \text{Z Diff.} \times \frac{\text{Increments}}{0^\circ.5} = (-)0^\circ.1 \times \frac{0^\circ.2}{0^\circ.5} = (+)0^\circ.0.$$

$$\text{L corr.} = \text{Z Diff.} \times \frac{\text{Increments}}{1^\circ} = (+)0^\circ.2 \times \frac{0^\circ.4}{1^\circ.0} = (+)0^\circ.1.$$

The error of the gyrocompass is found as shown in figure 719c.

	Actual	Base Arguments	Base Z	Tab* Z	Z Diff.	Increments	Correction +	Correction −

Gyro Error	1°.6E

*Respondent for two base arguments and 1° (30′ for d) change from the third base argument, in vertical order of t, d, and L.

FIGURE 719c.—Azimuth by Pub. No. 214.

Using Pub. No. 260, *Azimuths of the Sun*, to determine the azimuth, the tabular azimuth angles are interpolated for meridian angle, declination, and latitude.

In these tables, azimuth angles are given to the nearest 1′, at 10^m intervals of local apparent time from "sunrise" to "sunset" (center of the sun on the *celestial* horizon), with the LAT and the azimuth angle of these phenomena given at the bottom of each column. A separate table is given for each 1° of latitude from 0° to 70°. The first part of the book is a table for latitude 0°. The second part is devoted to tables of latitude and declination "same name". The third part gives "contrary name" tables. Declination entries are given at 1° intervals from 0° to 23°, with the approximate dates on which this is the declination of the sun. Extracts from these tables are given in appendix I. Values are customarily taken by triple interpolation, using the right-hand "PM" LAT column as meridian angle.

In the solution, the meridian angle is expressed in time units to the nearest $0^m.1$, and the declination and latitude in arc to the nearest 0°.1. The Z Diff. is the difference in minutes of arc between the tabulated value for the *nearest* values of t, d, and L, and the next value for the t, d, or L on the opposite side of the actual value. The increment is the difference between the actual value of t, d, and L and that used for entering the table.

Example 3.—In DR lat. 23°16′.1N, the azimuth of the sun is observed as 281°.7 pgc. At the time of the observation, the declination of the sun is 18°23′.7N; the meridian angle of the sun is 71°24′.3W.

Required.—The gyro error.

Solution.—By Pub. No. 260:

(1) Refer to appendix I. In this example the tabular azimuth angle used as base Z is compared with the tabular azimuth angle for the base declination and latitude, but meridian angle 4^h40^m to determine the Z Diff. for meridian angle. Similarly, the base Z is compared with the tabular value for the base meridian angle and latitude, but declination 19° to determine the Z Diff. for declination; and with the base values of meridian angle and declination, but latitude 24° to determine the Z Diff. for latitude.

(2) Interpolation is between whole degrees of declination and latitude, but 10^m of meridian angle.

$$\text{t corr.} = \text{Z Diff.} \times \frac{\text{Increments}}{10^m} = (+)48' \times \frac{4^m.4}{10^m} = (+)21'$$

$$\text{d corr.} = \text{Z Diff.} \times \frac{\text{Increments}}{1°} = (-)62' \times \frac{0°.4}{1°.0} = (-)25'$$

$$\text{L corr.} = \text{Z Diff.} \times \frac{\text{Increments}}{1°} = (+)25' \times \frac{0°.3}{1°.0} = (+)8'$$

The error of the gyrocompass is found as shown in figure 719d.

	Actual	Base Arguments	Base Z	Tab* Z	Z Diff.	Increments	Correction +	Correction −

Gyro Error	1°.0 W

*Respondent for two base arguments and 1° (10^m for t) change from the third base argument, in vertical order of t, d, and L.

FIGURE 719d.—Azimuth by Pub. No. 260.

In entering the table, one should keep in mind that values of t increase *upward* from the bottom of the page. Care should be used in locating meridian angle, for the manner of labeling the values can easily be misunderstood. For latitude 0°, Z is labeled N or S to agree with declination. Interpolation is made for t and d only, and the value converted to Zn. The Zn at latitude 1° is then computed, and interpolation for latitude is made between the two values of Zn.

Pub. No. 261, *Azimuths of Celestial Bodies*, extends the Pub. No. 260 tables by providing information in similar form (but with meridian angle increasing *downward* on the page) for declinations 24° to 70°. Tables for "same name" only are given. If latitude and declination are of contrary name, the tables are entered with the supplement of the meridian angle. The value taken from the table is then the supplement of the azimuth angle, which is labeled N or S to agree with the latitude and E or W to agree with the meridian angle. Extracts from Pub. No. 261 are given in appendix J.

Example 4.—In DR lat. 51°25′.5S, the declination of a body below the horizon is 57°41′.4N; the meridian angle of the body is 49°31′.6E.

Required.—The azimuth of the body.

Solution.—By Pub. No. 261:

(1) Refer to appendix J. Because the latitude and declination are of contrary name, the tables are entered with the supplement of the meridian angle.

(2) In this example the tabular azimuth angle used as the base Z is compared with the tabular azimuth angle for the base declination and latitude, but meridian angle 8^h50^m to determine the Z Diff. for meridian angle. Similarly, the base Z is compared with the tabular value for the base meridian angle and latitude, but declination 58° to determine the Z Diff. for declination; and with the base values of meridian angle and declination, but latitude 52° to determine the Z Diff. for latitude.

(3) Interpolation is between whole degrees of declination and latitude, but 10^m of meridian angle.

One step can be eliminated by considering the corrected value Z instead of 180°−Z, and labeling it N or S to agree with the declination. In this example the body is below the horizon.

The azimuth of the body is found as shown in figure 719e.

t 3h 18′.1E	Actual	Base Arguments	Base Z	Tab* Z	Z Diff.	Increments	Correction +	Correction −

FIGURE 719e.—Azimuth by Pub. No. 261.

720. Amplitudes.—For checking the compass, an azimuth observation of a celestial body at low altitude is desirable because it can be measured easiest and most accurately. If the body is observed when its center is on the *celestial* horizon, the **amplitude** (**A**), which is the arc of the horizon between the prime vertical and the body, can be taken directly from table 27.

The amplitude is given the prefix E (east) if the body is rising and W (west) if setting. It is given the suffix N if the body rises or sets north of the prime vertical (which it does if it has northerly declination) and S if it rises or sets south of the prime vertical (having southerly declination). The suffix is given to agree with the declination of the body. Interconversion of amplitude and azimuth is similar to that of azimuth angle and azimuth. Thus, if A=E15°S, the body is 15° south of east or 90°+15°= 105°. For any given body, the numerical value of amplitude would be the same at rising and setting if the declination did not change.

When the center of the sun is on the celestial horizon, its *lower limb* is about two-thirds of a diameter above the visible horizon. When the center of the moon is on the celestial horizon, its *upper limb* is on the visible horizon. When planets and stars are on the celestial horizon, they are a little more than one sun diameter above the visible horizon. In high latitudes, amplitudes should be observed on the visible horizon.

If the body is observed when its center is on the *visible horizon*, the *observed* value should be corrected by the value from table 28, using the rules given with the table, before comparison with the value taken from table 27. If preferred, the correction can be applied with reversed sign to the value taken from table 27 and compared with the uncorrected observed value. This is the procedure used if amplitude or azimuth is desired when the celestial body is on the visible horizon.

In the diagram on the plane of the celestial meridian shown in figure 720a, a celestial body of declination same name as latitude is on the celestial horizon at M; a celestial body having declination of contrary name is on the celestial horizon at M′. Triangles PnNM and PnNM′ are right spherical triangles, PnNM and PnNM′ being right angles.

Side NM of triangle PnNM is the coamplitude (90°−A); side PnN is the latitude; and side PnM is the codeclination (90°−d).

The formula for amplitude is derived by Napier's rules:

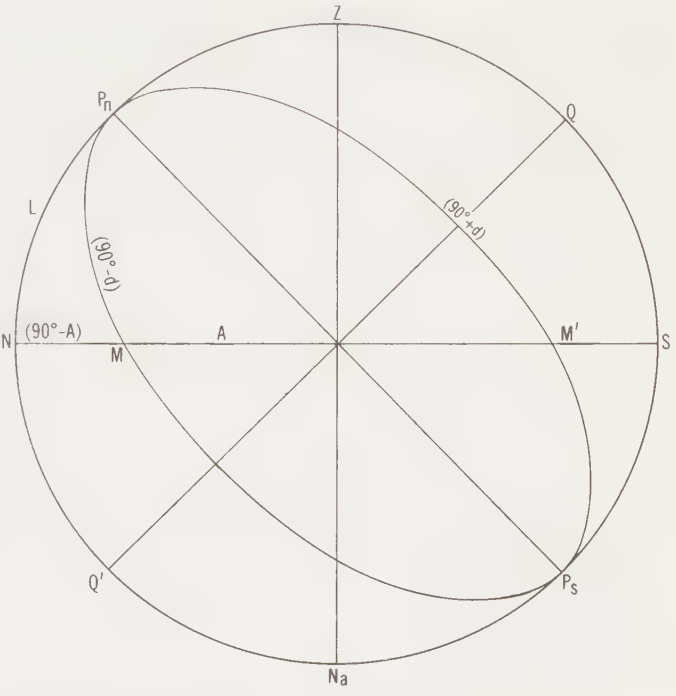

FIGURE 720a.—Diagram on plane of the celestial meridian.

The five sectors of the diagram for right spherical triangle PnNM are completed as in figure 720b. Applying Napier's rules:

$$\sin d = \cos L \cos (90° - A)$$
$$\sin d = \cos L \sin A$$
$$\sin A = \sec L \sin d. \qquad (13)$$

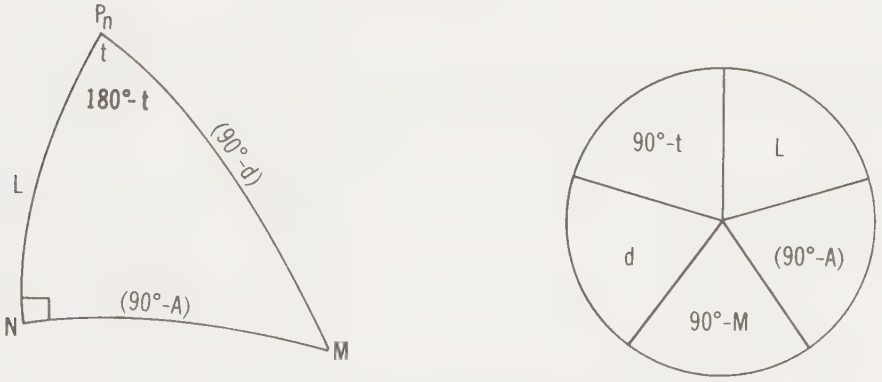

FIGURE 720b.—Circular parts diagram for spherical triangle PnNM.

For the contrary name case, side NM′ is (90°+A); side PnN is the latitude; and side PnM′ is (90°+d). The five sectors of the diagram for right spherical triangle PnNM′ are completed as in figure 720c. Applying Napier's rules:

$$\begin{aligned} -\sin d &= \cos L \cos(90°+A) \\ \cos(90°+A) &= -\sec L \sin d \\ \sin A &= \sec L \sin d, \end{aligned} \tag{13}$$

in which A is the amplitude, L is the latitude of the observer, and d is the declination of the celestial body. Table 27 was computed by means of this formula.

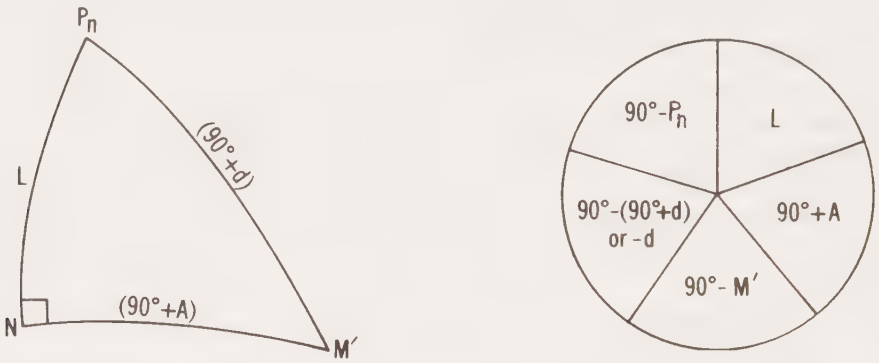

FIGURE 720c.—Circular parts diagram for spherical triangle PnNM′.

Example.—The DR latitude of a ship is 51°24′.6N, at a time when the declination of the sun is 19°40′.4N.

Required.—(1) The amplitude (A) when the center of the setting sun is on the celestial horizon.

(2) The amplitude when the center of the setting sun is on the visible horizon.

(3) The azimuth when the center of the setting sun is on the visible horizon.

Solution.—

(1) A W32°.6N (tab. 27)
T 28 1°.1S (rev.)—applied to *tabulated* amplitude
(2) A W33°.7N
(3) Zn 303°.7.

721. Finding time on the prime vertical.—A celestial body having a declination of opposite name to the latitude crosses the prime vertical below the horizon. Its nearest visible approach is at the time of rising and setting.

If a celestial body has a declination of the same name as the latitude, but is numerically *greater*, it does not cross the prime vertical. Its nearest approach (in azimuth) is at the point at which its azimuth angle is maximum. At this point the meridian angle is given by the formula

$$\sec t = \tan d \cot L, \tag{14a}$$

and its altitude by the formula

$$\csc h = \sin d \csc L. \tag{14b}$$

A celestial body having a declination of the same name as the latitude, and numerically *smaller*, crosses the prime vertical at some point before it reaches the celestial meridian, and again after meridian transit. At these two crossings of the prime vertical, the meridian angles are equal and are always less than 90°. They are given by the formula

$$\cos t = \tan d \cot L. \tag{14c}$$

The altitudes are also equal, and are given by the formula

$$\sin h = \sin d \csc L. \tag{14d}$$

Meridian angle and altitude of bodies on the prime vertical, and similar data for the nearest approach (in azimuth) of those bodies of same name which do not cross the prime vertical, are given in table 25 for various latitudes, and for declinations from 0° to 23°, inclusive.

Equation 14c for meridian angle, when azimuth angle is 90°, is derived by Napier's rules as follows:

The circular parts diagram for astronomical triangle PMZ is completed as shown in figure 721.

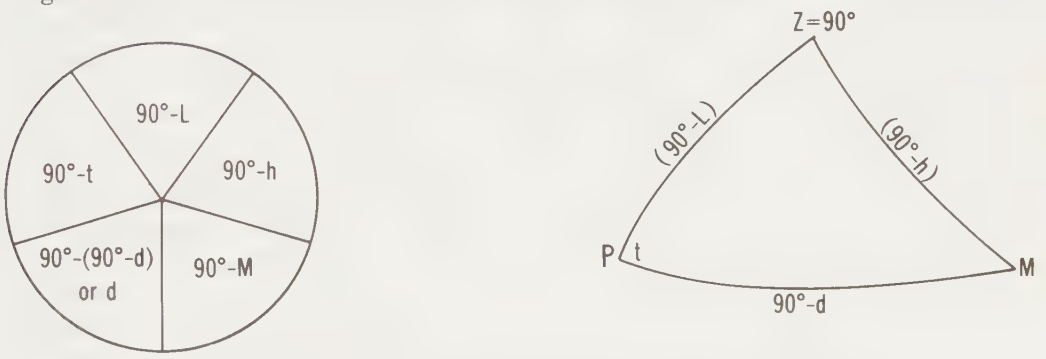

FIGURE 721.—Circular parts diagram for astronomical triangle PMZ.

$$\sin (90° - t) = \tan d \tan (90° - L)$$
$$\cos t = \tan d \cot L. \tag{14c}$$

The altitudes of the two crossings of the prime vertical are also equal. Equation 14d for altitude on the prime vertical is derived by Napier's rules:

$$\sin d = \cos(90° - L) \cos(90° - h)$$
$$\sin d = \sin L \sin h$$
$$\sin h = \sin d \csc L. \tag{14d}$$

To find the *time* of crossing the prime vertical, convert t to LHA, and add west longitude or subtract east longitude to find GHA. The GMT at which this GHA occurs can be found, as explained in article 733, and converted to any other time desired.

Example.—Determine (1) the approximate zone time, and (2) the approximate altitude of the sun when it crosses the prime vertical during the afternoon of May 30, 1975, at lat. 51°32′.3N, long. 160°21′.7W, using table 25 and the *Nautical Almanac*.

Solution.—

	May 30
t	71°.6W (from table 25)
LHA	71°.6
λ	160°.4W
GHA	232°.0
3^h	225°.6
26^m	6°.4
GMT	0326 May 31
ZD(+)	11 (rev.)
(1) ZT	1626 May 30
(2) h	28°.4 (from table 25).

At the time of crossing the prime vertical, or at nearest approach (in azimuth), a celestial body is changing azimuth slowly, and therefore this is considered a good time to check compass deviation or to swing ship.

The prime vertical at any place is the celestial horizon of a point 90° away, on the same meridian. Therefore, a celestial body crosses the prime vertical at approximately the same time it rises and sets at the point 90° away. Thus, if one is at latitude 35° N, the sun crosses his prime vertical at about the same time it rises or sets at latitude 55°S. If time of sunrise and sunset are to be obtained accurately by this method, corrections must be applied for semidiameter and refraction.

Dip and Distance of the Horizon

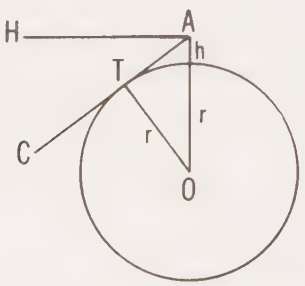

FIGURE 722a.—Dip without refraction.

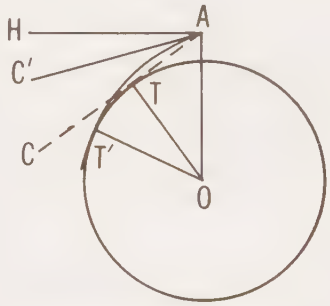

FIGURE 722b.—Dip with refraction.

722. Dip of geometrical horizon.—If there were no refraction, dip would be the angle between the horizontal at the eye of the observer, and a straight line from this point tangent to the surface of the earth at the geometrical horizon. In figure 722a, the eye of the observer is at A at height h above the surface of the earth of radius r. The line AH is the horizontal through A, and the straight line AC is tangent to the earth's surface at T. Angle HAC is the dip (D) at A, neglecting refraction. Since OA is perpendicular to AH and OT is perpendicular to AC, angle AOT is equal to angle HAC (art. 127).

$$\tan D = \tan AOT = \frac{AT}{OT} = \frac{AT}{r}.$$

From geometry,

$$AT = \sqrt{h(2r+h)}.$$

Accordingly,

$$\tan D=\frac{1}{r}\sqrt{2rh+h^2}$$

$$\tan^2 D=\frac{2rh+h^2}{r^2}=\frac{2h}{r}+\left(\frac{h}{r}\right)^2$$

$$\tan D=\sqrt{\frac{2h}{r}+\left(\frac{h}{r}\right)^2}.$$

Since h is very small compared with r, the square of the fraction $\left(\frac{h}{r}\right)$ can be discarded without appreciable effect.

Then, $\tan D=\sqrt{\frac{2h}{r}}$, approximately.

Using 20.902×10^6 feet as the mean radius of the earth and expressing h in feet,

$$\tan D=\sqrt{\frac{2h}{20.902\times10^6}}.$$

With D expressed in minutes of arc,

$$D \tan 1'=\sqrt{\frac{2h}{20.902\times10^6}}$$

$$D=1.06\sqrt{h}.$$

723. Distance of geometrical horizon.—A straight line from the eye of the observer tangent to the earth leads to the geometrical horizon. In figure 722a the geometrical horizon of the observer at A is at point T; the distance of the geometrical horizon is the arc of the circle subtending the central angle AOT. Therefore, when neglecting refraction, the numerical value of the dip, in minutes of arc, is equal to the distance to the geometrical horizon, in nautical miles. Or,

$$d=1.06\sqrt{h}, \tag{15}$$

where h is the height of eye in feet and d is the distance of the geometrical horizon in nautical miles.

724. Distance of visible horizon.—The line of sight to the horizon passes through regions of different densities adjacent to the earth's surface. Consequently, the ray of light from the horizon to the observer's eye is bent by refraction. The normal result of this *terrestrial refraction* is to increase the distance to the horizon, which is at T′ of figure 722b, instead of at T. This actual distance, under normal conditions, is given in table 8. Although the horizon is farther away than it would be if there were no refraction, it appears *higher* for the eye of the observer does not detect the curvature of the line of sight. Therefore, the horizon *appears* to be at C′ instead of at C.

The angle HAC′ is the dip of the visible horizon, i.e., dip with allowance made for refraction. The angle of refraction R is C′AC.

In figure 724a, line PC is tangent to the earth's surface at T′. The curved path of the ray of light from A to T′ may be regarded as the arc of a circle. Then refraction elevates point A as seen from T′ as much as it elevates T′ as seen from A. The observer at T′ would see point A at P. On drawing the chord T′A, the angle PT′A may be taken as equal to angle C′AC, the angle of refraction. This refraction is equal to 0.0784D, where D is the dip of the horizon neglecting refraction.

With the small heights of eye considered, angle T′AP of triangle T′PA is nearly a right angle. Setting x=PA, we may take without appreciable error

$$x=T'A \tan PT'A=r \tan D\times 0.0784 \tan D.$$

But, $r \tan^2 D=2h$.

Hence, $x=0.1568\ h$.

From geometry,

$$PT'=\sqrt{(2\ OB+PB)\times PB}=\sqrt{2r\ (x+h)}, \text{ approximately}$$

PT'=distance to visible horizon d

$$\therefore d=\sqrt{2.3136rh}.$$

Using 20.902×10^6 feet as the mean radius of the earth and expressing h in feet, the distance to the visible horizon, d, in nautical miles is given by:

$$d=\frac{1}{6076.1}\sqrt{2.3136\times 20.902\times 10^6\ h}$$

$$d=1.144\sqrt{h}. \tag{16}$$

Example.—The height of eye of the observer is 49 feet.
Required.—Distance to the visible horizon.
Solution.—By equation 16:

$$d=1.144\sqrt{49}=1.144\times 7$$

$$d=8.0 \text{ n.mi.}$$

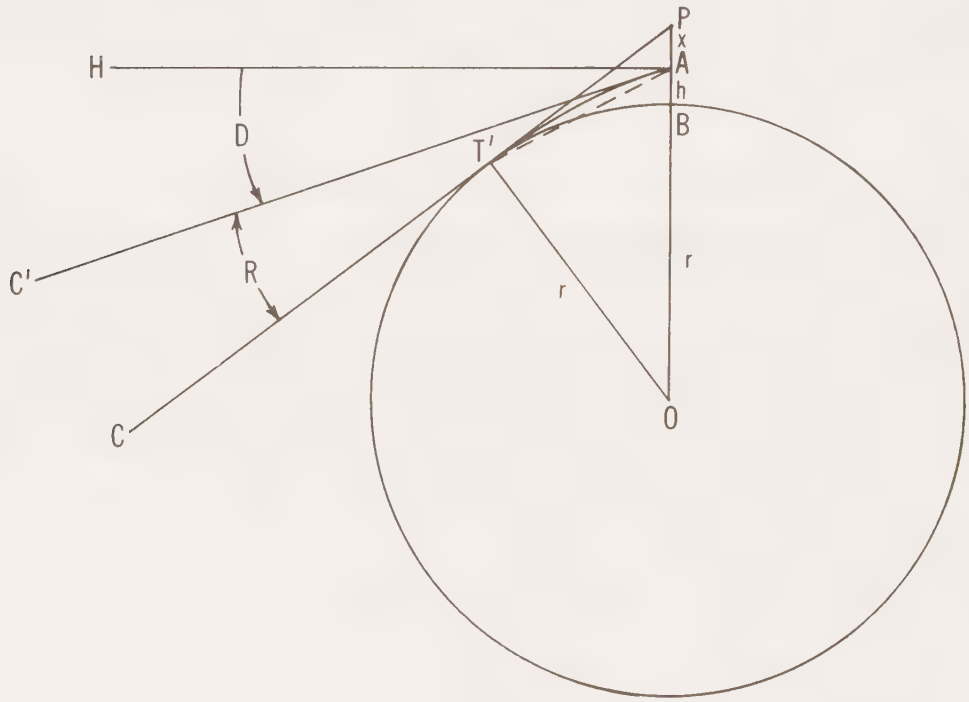

FIGURE 724a.—Effect of refraction on distance of visible horizon.

725. Dip of visible horizon.—The dip of the visible horizon (D) is the angle HAC′ of figure 724a, the angle between the horizontal at the eye of the observer and a straight line tangent at A to the curved ray of light from the visible horizon.

The dip in terms of d and R is determined as follows:

$$\begin{aligned} &AOT'+OT'A+OAT'=180° \\ &d+(90°-R)+(90°-D-R)=180° \\ &D=d-2R. \end{aligned}$$

With $d=1.144\sqrt{h}$ and substituting $R=0.0784d$,

$$D=0.97\sqrt{h}. \tag{17}$$

Example.—The height of eye of the observer is 36 feet.
Required.—The dip of the visible horizon.
Solution.—By equation 17:

$$D=0.97\sqrt{h}=0.97\sqrt{36}=0.97\times 6$$
$$D=5'.8.$$

726. Dip short of the horizon.—If land, another ship, or other obstruction is between the observer and his sea horizon, an altitude can be measured by using the waterline of the obstruction as a horizontal reference, if its distance from the observer is known. In this case the dip is greater than that given in the almanacs. Table 22 gives the values to be used.

Table 22 was computed by means of a formula derived as follows:

In figure 726b, point S is on a waterline between the observer at O and his sea horizon at T. If the observer were at point A, his sea horizon would be at S where a curved ray of light from A is tangent to the surface of the sea.

The distance of the sea horizon, in nautical miles, as seen from A at height h′, in feet, and the distance to the waterline short of the sea horizon is given by equation 16:

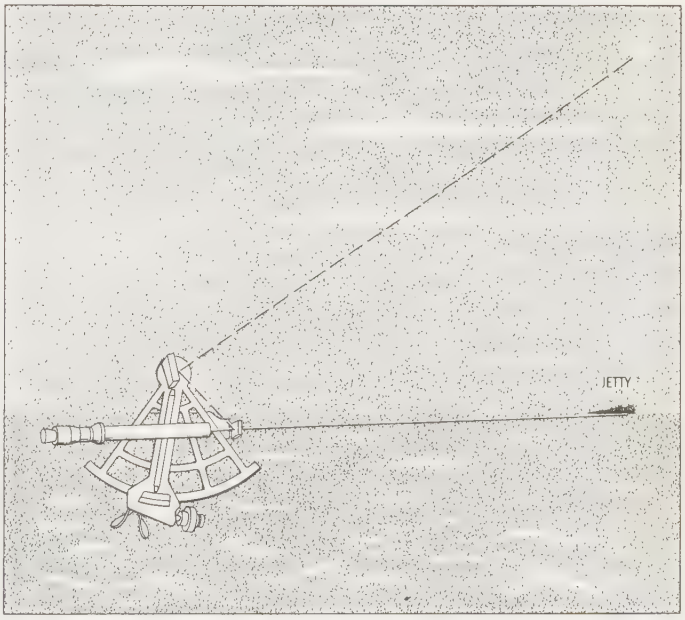

FIGURE 726a.—Measuring altitude short of the horizon.

$$d=1.144\sqrt{h'}.$$

The dip of S as seen from A is given by equation 17:

$$D=0'.97\sqrt{h'}.$$

With $d=1.144\sqrt{h'}$,

$$D=\frac{0.97d}{1.144}=0.8479d.$$

With chords SA and SO drawn, as in figure 726b,

$$\angle AOS = \angle BAS - \angle ASO$$

because exterior angle BAS is equal to the sum of the two opposite interior angles.

For small angle ASO, $\tan ASO = \frac{AO}{SA}$, without appreciable error.

Since SA is very nearly equal to d in nautical miles and $\tan n' = n \tan 1'$ for small angles,

$$\angle ASO = \frac{h - h'}{6076d \tan 1'}.$$

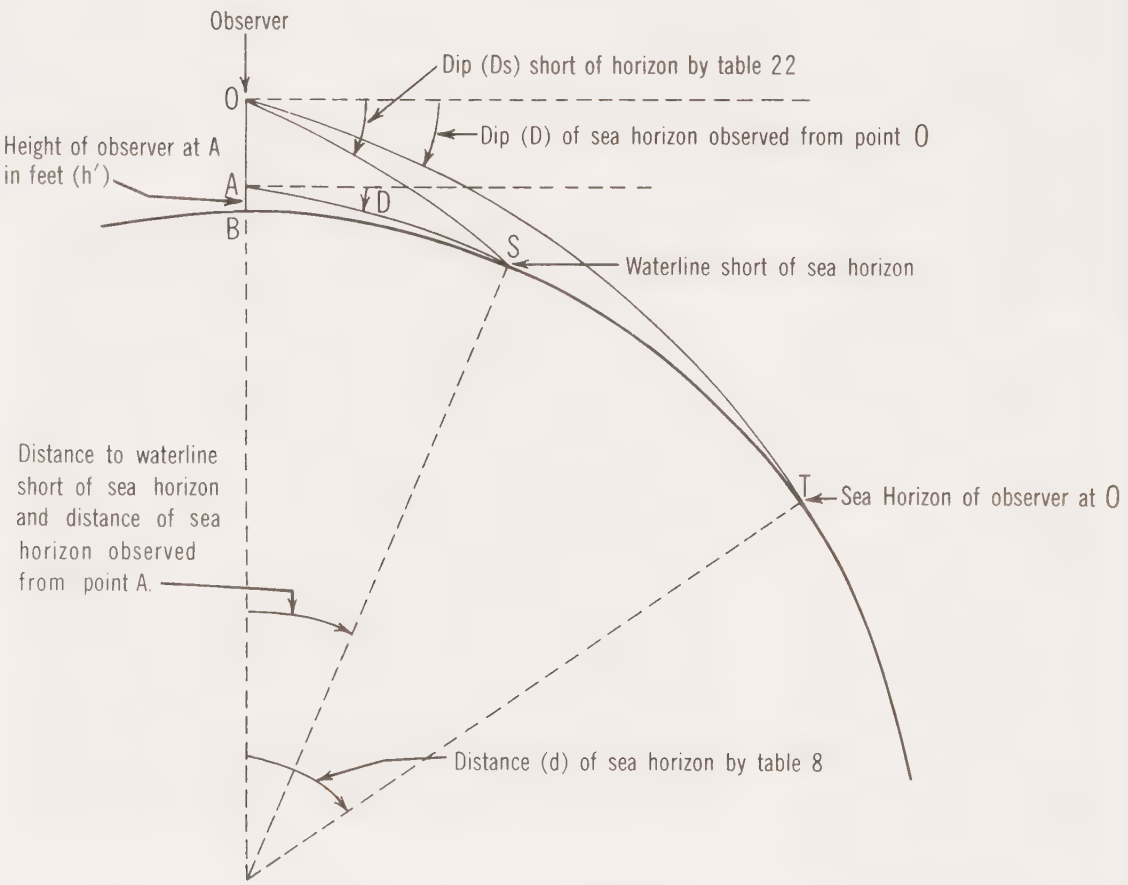

FIGURE 726b.—Dip short of the horizon.

In figure 726b, D is the dip of S as seen from A. Then, since the sum of the interior angles of a plane triangle is equal to 180°,

$$D + 90° + \angle ASO + (90° - D_s) = 180°$$
$$D_s = D + \angle ASO.$$

Since the dip short of the horizon (D_s) is equal to the dip as seen from A(0′.8479d) plus ∠ASO (sum of interior angles of plane triangle is equal to 180°),

$$D_s = 0'.8479d + \frac{h - h'}{6076d \tan 1'}$$

$$\text{Substituting } h' = \left(\frac{d}{1.144}\right)^2,$$

$$D_s = 0.4156d + 0.5658 \frac{h}{d}. \qquad (18)$$

Rising, Setting, and Twilight

727. Rising, setting, and twilight.—In both almanacs the times of sunrise, sunset, moonrise, moonset, and twilight information at various latitudes between 72°N and 60°S are given to the nearest whole minute. By definition, rising or setting occurs when the *upper* limb of the body is on the *visible* horizon, assuming standard refraction for zero height of eye. Because of variations in refraction and height of eye, computation to a greater precision than 1^m is not justified.

In high latitudes some of the phenomena do not occur during certain periods. The symbols used to indicate this condition are:

▭ Sun or moon does not set, but remains continuously above the horizon.

▬ Sun or moon does not rise, but remains continuously below the horizon.

//// Twilight lasts all night.

The *Nautical Almanac* makes no provision for finding the times of rising, setting, or twilight in polar regions. The *Air Almanac* has graphs for this purpose.

In the *Nautical Almanac*, sunrise, sunset, and twilight tables are given only once for the middle of the three days on each page opening. For most purposes this information can be used for all three days. Both almanacs have moonrise and moonset tables for each day.

The tabulations are in local mean time (art. 610). On the zone meridian, this is the zone time (ZT). For every 15′ of longitude that the observer's position differs from that of the zone meridian, the zone time of the phenomena differs by 1^m, being *later* if the observer is *west* of the zone meridian, and *earlier* if he is *east* of the zone meridian. The local mean time of the phenomena varies with latitude of the observer, declination of the body, and hour angle of the body relative to that of the mean sun.

Sunrise and sunset are also tabulated in the tide tables (from 76°N to 60°S) and in a supplement to the American ephemeris of 1946 entitled *Tables of Sunrise, Sunset, and Twilight* (from 75°N to 75°S). The meridian angle of any body at the time of its rising and setting can be computed by the formulas given in article 715. The data concerning the rising and setting of the sun and moon and the duration of twilight for high southern latitudes are published as graphs in United States Naval Observatory Circular No. 147, *Sunlight, Moonlight, and Twilight for Antarctica*; these graphs are similar to the graphs in the *Air Almanac* for northern latitudes (art. 730).

728. Finding time of sunrise and sunset.—*Nautical Almanac*. Enter the table on the daily page, and extract the LMT for the tabulated latitude next *smaller* than the observer's latitude (unless this is an exact tabulated value). Apply a correction from table I on almanac page xxxii to interpolate for latitude, determining the sign of the correction by inspection. Then convert LMT to ZT by means of the difference in longitude (dλ) between the local and zone meridians.

Example.—Find the zone time of sunrise and sunset at lat. 43°31′.4N, long. 36°14′.3W on June 1, 1975.

Solution.—

L 43°31′.4N June 1
λ 36°14′.3W

Sunrise		Sunset	
40°	0433	40°	1922
T I	(−)11	T I	(+)11
LMT	0422	LMT	1933
dλ	(+)25	dλ	(+)25
ZT	0447	ZT	1958

Air Almanac. The procedure is the same as that for the *Nautical Almanac*, except that the LMT is extracted from the tables of sunrise and sunset instead of the daily page, and latitude correction is by linear interpolation.

The tabulated times are for the Greenwich meridian. Except in high latitudes near the times of the equinoxes, the time of sunrise and sunset varies so little from day to day that no interpolation is needed for longitude. If such an interpolation is considered justified, it can be made in the same manner as for the moon (art. 730).

In high latitudes, interpolation is not always possible. For instance, on June 1 1975, sunrise at latitude 66°N occurs at 0115, but at latitude 68°N the sun does not set. Between these two latitudes the time of sunrise might be found from the graphs in the *Air Almanac*, or by computation, as explained in article 715. However, in such a marginal situation, the time of sunrise itself is uncertain, being greatly affected by a relatively small change of refraction or height of eye.

729. Finding time of twilight.—Morning twilight *ends* at sunrise, and evening twilight *begins* at sunset. The time of the darker limit can be found from the almanacs. The *time* of the darker limits of both *civil* and *nautical* twilights (center of the sun 6° and 12°, respectively, below the celestial horizon) is given in the *Nautical Almanac*. The *Air Almanac* provides tabulations of civil twilight from 60°S to 72°N. The brightness of the sky at any given depression of the sun below the horizon may vary considerably from day to day, depending upon the amount of cloudiness and other atmospheric conditions. In general, however, the most effective period for observing stars and planets occurs when the center of the sun is between about 3° and 9° below the celestial horizon. Hence, the darker limit of civil twilight occurs at about the mid point of this period. At the darker limit of nautical twilight the horizon is generally too dark for good observations. At the darker limit of *astronomical twilight* (center of the sun 18° below the celestial horizon) full night has set in. The time of this twilight is given in the ephemeris. Its approximate value can be determined by extrapolation (art. 207) in the *Nautical Almanac*, noting that the duration of the different kinds of twilight is not proportional to the number of degrees of depression at the darker limit. More precise determination of the time at which the center of the sun is any given number of degrees below the celestial horizon can be determined by a large-scale diagram on the plane of the celestial meridian (art. 507) or by computation (art. 715). Duration of twilight in latitudes higher than 65°N is given in a graph in the *Air Almanac*.

Nautical Almanac. The method of finding the darker limit of twilight is the same as that for sunrise and sunset (art. 728).

Example 1.—Find the zone time of beginning of morning nautical twilight and ending of evening nautical twilight at lat. 21°54′.7S, long. 109°34′.2E on June 1, 1975.

Solution.—

L 21°54′.7 S June 1
λ 109°34′.2 E

	Nautical twilight		Nautical twilight
20° S	0537	20° S	1819
T I	(+)3	T I	(−)3
LMT	0540	LMT	1816
dλ	(−)18	dλ	(−)18
ZT	0522	ZT	1758

Air Almanac. The method of finding the darker limit of twilight is the same as that for sunrise and sunset as explained in article 728.

Example 2.—Find the zone time of beginning of morning civil twilight and ending of evening civil twilight at lat. 47°18′.8S, long. 87°28′.3W on June 1, 1975.

Solution.—

L 47°18′.8 S June 1
λ 87°28′.3 W

	Civil Twilight		Civil Twilight
45° S	0654	45° S	1701
corr.	(+)7	corr.	(−)7
LMT	0701	LMT	1654
dλ	(−)10	dλ	(−)10
ZT	0651 (twilight)	ZT	1644 (twilight)

Sometimes in high latitudes the sun does not rise but twilight occurs. This is indicated in the *Air Almanac* by the symbol ■ in the sunrise and sunset column. To find the time of beginning of morning twilight, *subtract* half the duration of twilight as obtained from the duration of twilight graph from the time of meridian transit of the sun; and for the time of ending of evening twilight, *add* it to the time of meridian transit. The LMT of meridian transit never differs by more than $16^{m}.4$ (approximately) from 1200. The actual time on any date can be determined from the almanac.

730. Finding time of moonrise and moonset is similar to finding time of sunrise and sunset, with one important difference. Because of the moon's rapid change of declination, and its fast eastward motion relative to the sun, the time of moonrise and moonset varies considerably from day to day. These changes of position on the celestial sphere (art. 501) are continuous, as moonrise and moonset occur successively at various longitudes around the earth. Therefore, the change in time is distributed over all longitudes. For precise results, it would be necessary to compute the time of the phenomena at any given place, by the method described in article 715. For ordinary purposes of navigation, however, it is sufficiently accurate to interpolate between consecutive moonrises or moonsets at the Greenwich meridian. Since apparent motion of the moon is westward, relative to an observer on the earth, interpolation in west longitude is between the phenomenon on the given date and the *following* one. In east longitude it is between the phenomenon on the given date and the *preceding* one.

Nautical Almanac. For the given date, enter the daily-page table with latitude, and extract the LMT for the tabulated latitude next *smaller* than the observer's latitude (unless this is an exact tabulated value). Apply a correction from table I of the al-

manac "Tables for Interpolating Sunrise, Moonrise, etc." to interpolate for latitude, determining the sign of the correction by inspection. Repeat this procedure for the day following the given date, if in west longitude; or for the day preceding, if in east longitude. Using the difference between these two times, and the longitude, enter table II of the almanac "Tables for Interpolating Sunrise, Sunset, etc." and take out the correction. Apply this correction to the LMT of moonrise or moonset at the Greenwich meridian on the given date to find the LMT at the position of the observer. The sign to be given the correction is such as to make the corrected time fall between the times for the two dates between which interpolation is being made. This is nearly always positive (+) in west longitude and negative (−) in east longitude. Convert the corrected LMT to ZT.

Example 1.—Find the zone time of moonrise and moonset at lat. 58°23′.6N, long. 144°07′.5W on June 1, 1975, using the *Nautical Almanac*.

Solution.—

L 58°23′.6N June 1
λ 144°07′.5W

dλ	(−)24		dλ	(−)24	
ZT	2349	May 31	ZT	1113	June 1

Air Almanac. For the given date, determine LMT for the observer's latitude at the Greenwich meridian, in the same manner as with the *Nautical Almanac*, except that linear interpolation is made directly from the main tabulation, since no interpolation table is provided. Extract, also, the value from the "Diff." column to the right of the moonrise and moonset column, interpolating if necessary. This "Diff." is one-fourth of the difference between the succeeding and preceding value, which is approximately one-half of the daily difference. The error introduced by this approximation is generally not more than a few minutes, although it increases with latitude. Using this difference, and the longitude, enter the "Interpolation of Moonrise, Moonset" table on flap F4 of the *Air Almanac* and take out the correction. The *Air Almanac* recommends the taking of the correction from this table without interpolation. The results thus obtained are sufficiently accurate for ordinary purposes of navigation. If greater accuracy is desired, the correction can be taken by interpolation. However, since the "Diff." itself is an approximation, the *Nautical Almanac* or computation (art. 715) should be used if accuracy is a consideration. Apply the correction to the LMT of moonrise or moonset at the Greenwich meridian on the given date to find the LMT at the position of the observer. The correction is positive (+) for west longitude, and negative (−) for east longitude, unless the "Diff." on the daily page is preceded by a negative sign (−), when the correction is negative (−) for west longitude, and positive (+) for

east longitude. If the time is near midnight, record the date at each step, as in the *Nautical Almanac* solution.

Example 2.—Find the zone time of moonrise and moonset at lat. 58°23′.6N, long. 144°07′.5W on June 1, 1975, using the *Air Almanac.*

Solution.—

L 58°23′.6N June 1
λ 144°07′.5W

	Moonrise		Moonset
diff.	(+)07	diff.	(+)36

corr.	(+)4	corr.	(+)29
LMT	0012	LMT	1138
dλ	(−)24	dλ	(−)24
ZT	2348 May 31	ZT	1114

As with the sun, there are times in high latitudes when interpolation is inaccurate or impossible. At such periods, the times of the phenomena themselves are uncertain, but an approximate answer can be obtained by moonlight graph in the *Air Almanac* or by computation, as explained in article 715. With the moon, this condition occurs when the moon rises or sets at one latitude, but not at the next higher tabulated latitude, as with the sun. It also occurs when the moon rises or sets on one day but not on the preceding or following day. This latter condition is indicated in the *Air Almanac* by the symbol ⁎ in the "Diff." column.

Because of the eastward revolution of the moon around the earth, there is one day each synodical month (29½ days) when the moon does not rise, and one day when it does not set. These occur near last quarter and first quarter, respectively. Since this day is not the same at all latitudes or at all longitudes, the time of moonrise or moonset found from the almanac may occasionally be the preceding or succeeding one to that desired. When interpolating near midnight, one should exercise caution to prevent an error.

Refer to the right-hand daily page of the *Nautical Almanac* for June 12, 13, 14 (app. F). On June 13 moonset occurs at 2350 at latitude 70°N, and at 0031 at latitude 72°N. These are *not* the same moonset, the one at 0031 occurring approximately one day *later* than the one occurring at 2350. This is indicated by the two times, which differ by nearly 24 hours. The table indicates that with increasing northerly latitude, moonset occurs *later*. Between 70°N and 72°N the time crosses midnight *to the following* day. Hence, between these latitudes interpolation should be made between 2350 on June 13 and 0007 on June 14.

The effect of the revolution of the moon around the earth is to cause the moon to rise or set *later* from day to day. The daily retardation due to this effect does not differ greatly from 50^m. The change in declination of the moon may increase or decrease this effect. The effect due to change of declination increases with latitude, and in extreme conditions it may be greater than the effect due to revolution of the moon. Hence, the interval between successive moonrises or moonsets is more erratic in high latitudes than in low latitudes. When the two effects act in the same direction, daily differences can be quite large. Thus, at latitude 72°N the moon rises at 0550 on June 13, and at 0806 on June 14. When they act in opposite directions, they are small, and when the effect due to change in declination is larger than that due to revolution, the moon sets

earlier on succeeding days. Thus, at latitude 72°N the moon sets at 0031 on June 13, and at 0007 on June 14. This condition is reflected in the *Air Almanac* by a negative "Diff." If this happens near last quarter or first quarter, two moonrises or moonsets might occur on the same day, one a few minutes after the day begins, and the other a few minutes before it ends. On June 14, 1975, for instance, at latitude 72°N, the moon sets at 0007, rises at 0806, and sets again at 2350 the same day. On those days on which no moonrise or no moonset occurs, the next succeeding one is shown with 24^h added to the time. Thus, at latitude 68°N the moon rises at 2342 on May 25, while the next moonrise occurs 24^h45^m later, at 0027 on May 27. This is listed both as 2427 on May 26 and as 0027 on May 27 (not shown in app. F).

Interpolation for longitude is always made between *consecutive* moonrises or moonsets, regardless of the days on which they fall.

Example 3.—Find the zone time of moonset at lat. 71°38′.7N, long. 56°21′.8W during the night of June 13–14, 1975, using the *Nautical Almanac*.

Solution.—

L 71°38′.7N June 13–14
λ 56°21′.8W

	Moonset	
70°N	2350	June 13
T I	(+)15	
LMT (G)	0005	June 14
70°N	2342	June 14
T I	(+)7	
LMT (G)	2349	June 14
LMT (G)	0005	June 14
diff.	16	
T II	(−)2	
LMT (G)	0005	June 14
LMT	0003	June 14
dλ	(−)15	
ZT	2348	June 13

Interpolation for the first entry is between 2350 on June 13 (lat. 70°N) and 0007 on June 14 (lat. 72°N); for the second entry, between 2342 on June 14 and 2350 on June 14.

Beyond the northern limits of the almanacs the values can be obtained from a series of graphs given near the back of the *Air Almanac*. These graphs are shown in appendix G. For high latitudes, graphs are used instead of tables because graphs give a clearer picture of conditions, which may change radically with relatively little change in position or date. Under these conditions interpolation to practical precision is simpler by graph than by table. In those parts of the graph which are difficult to read, the times of the phenomena's occurrence are themselves uncertain, being altered considerably by a relatively small change in refraction or height of eye.

On all of these graphs any given latitude is represented by a horizontal line, and any given date by a vertical line. At the intersection of these two lines the duration is read from the curves, interpolating by eye between curves.

The "Semiduration of Sunlight" graph gives the number of hours between sunrise and meridian transit or between meridian transit and sunset. The dot scale near the top of the graph indicates the LMT of meridian transit, the time represented by the

minute dot nearest the vertical date line being used. If the intersection occurs in the area marked "sun above horizon," the sun does not set; and if in the area marked "sun below horizon," the sun does not rise.

Example 1.—Find the zone time of sunrise and sunset at lat. 71°30′.0N, long. 10°00′.0W near Jan Mayen Island, on August 25, 1975.

Solution.—

	August 25	
LMT	1202	LAN, from top of graph
dλ	(−)20	
ZT	1142	LAN
semidur.	840	from graph
ZT	0302	sunrise (−semidur.)
ZT	2022	sunset (+semidur.)

A vertical line through August 25 passes nearest the dot representing LAN 1202 on the scale near the top of the graph. This is LMT; at longitude 10°00′.0 W the ZT is 20^m earlier, or at 1142. The intersection of the vertical date line with the horizontal latitude line occurs between the 8^h and 9^h curves, at approximately 8^{h}40^m. Hence, sunrise occurs at this interval before LAN and sunset at this interval after LAN.

The "Duration of Twilight" graph gives the number of hours between the beginning of morning *civil* twilight (center of sun 6° below the horizon) and sunrise, or between sunset and the end of evening civil twilight. If the sun does not rise, but twilight does occur, the time taken from the graph is half the total length of the single twilight period, or the number of hours from beginning of morning twilight to LAN, or from LAN to end of evening twilight. If the intersection occurs in the area marked "continuous twilight or sunlight," the center of the sun does not get more than 6° below the horizon; and if in the area marked "no twilight nor sunlight," the sun remains more than 6° below the horizon throughout the entire day.

Example 2.—Find the zone time of beginning of morning twilight and ending of evening twilight at the place and date of example 1.

Solution.—

Twilight	
ZT 0302	sunrise, from example 1
dur. 153	from graph
ZT 0109	morning twilight

Twilight	
ZT 2022	sunset, from example 1
dur. 153	from graph
ZT 2215	evening twilight

The intersection of the vertical date line and the horizontal latitude line occurs approximately one-sixth of the distance from the 2^h line toward the 1^{h}20^m line; or at about 1^{h}53^m. Morning twilight begins at this interval before sunrise, and evening twilight ends at this interval after sunset.

The "Semiduration of Moonlight" graph gives the number of hours between moonrise and meridian transit or between meridian transit and moonset. The dot scale near the top of the graph indicates the LMT of meridian transit, each dot representing one hour. The phase symbols indicate the date on which the principal moon phases occur, the open circle indicating full moon and the dark circle indicating new moon. If the intersection of the vertical date line and the horizontal latitude line falls in the "moon above horizon" or "moon below horizon" area, the moon remains above or below the horizon, respectively, for the entire 24 hours of the day.

If approximations of the times of moonrise and moonset are sufficient, the values of semiduration taken from the graph can be used without adjustment. For more

accurate results, the times on the required date and the adjacent date (the following date in west longitude and the preceding date in east longitude) should be determined, and an interpolation made for longitude, as in any latitude, since the intervals given are for the Greenwich meridian.

Example 3.—Find the zone time of moonrise and moonset at lat. 74°00′.0N, long. 108°00′.0W on May 8, 1975, and the phase of the moon on this date.

Solution.—

May 8		May 9	
LMT	0923	LMT	1006 meridian transit, from graph
dλ	(+)12	dλ	(+)12
ZT	0935	ZT	1018 meridian transit
semidur.	7^h59^m	semidur.	9^h15^m from graph
ZT	0136	ZT	0103 (moonrise—semidur.)
ZT	1734	ZT	1933 (moonset + semidur.)

Moonrise		Moonset	
ZT	0136 May 8	ZT	1734 May 8
ZT	0103 May 9	ZT	1933 May 9
diff.	(−)33	diff.	(+)119
33×108.0/360	(−)10	119×108.0/360	(+)36
ZT	0126	ZT	1810

The phase is crescent, about two days before new moon. The LMT of meridian transits are found by noting the intersections of the vertical date lines with the dot scale near the top of the graph, interpolating by eye. At longitude 108°00′.0 W the ZT is 12^m later. The semiduration is found by noting the position, with respect to the semiduration curves, of the intersection of the vertical date line with the horizontal latitude line. This interval is subtracted from the time of meridian transit to obtain moonrise, and added to obtain moonset. These solutions are made for both May 8 and 9, and the difference determined in minutes. The adjustment to be applied to the ZT on May 8 at Greenwich is determined by multiplying this difference by the ratio λ/360. The phase is determined by noting the position of the vertical date line with respect to the phase symbols. If the answer indicates that the phenomenon occurs on a date differing from that desired, a new solution should be made, adjusting the starting date accordingly. The phenomenon may occur twice on the same day, or it may not occur at all. In high latitudes the effect on the time of moonrise and moonset of a relatively small change in declination is considerably greater than in lower latitudes, resulting in greater differences from day to day.

Sunlight, twilight, and moonlight graphs are not given for south latitudes. Beyond latitude 65°S, the northern hemisphere graphs can be used for determining the semiduration or duration, by using the vertical date line for a day when the declination has the same numerical value but opposite sign. The time of meridian transit and the phase of the moon are determined as explained above, using the correct date. Between latitudes 60°S and 65°S solution is made by interpolation between the tables and the graphs.

Several other methods of solution of these phenomena are available. The *Tide Tables* tabulate sunrise and sunset from latitude 76°N to 60°S. A supplement to the American Ephemeris of 1946, entitled *Tables of Sunrise, Sunset, and Twilight*, provides

tabulations from latitude 75°N to 75°S and graphs for semiduration of sunlight and duration of twilight, with separate graphs for civil, nautical, and astronomical twilights. Semiduration or duration can be determined graphically by means of a diagram on the plane of the celestial meridian (art. 507), or by computation. When computation is used, solution is made for the meridian angle at which the required negative altitude occurs. The meridian angle expressed in time units is the semiduration in the case of sunrise, sunset, moonrise, and moonset; and the semiduration of the combined sunlight and twilight, or the time from meridian transit at which morning twilight begins or evening twilight ends. For sunrise and sunset the altitude used is (−)50′. Allowance for height of eye can be made by algebraically subtracting (numerically adding) the dip correction from this altitude. The altitude used for twilight is (−)6°, (−)12°, or (−)18° for civil, nautical, or astronomical twilight, respectively. The altitude used for moonrise and moonset is −34′−SD+HP, where SD is semidiameter and HP is horizontal parallax, from the daily pages of the *Nautical Almanac*.

731. Rising, setting, and twilight at a moving craft.—Instructions given in the preceding three articles relate to a fixed position on the earth. Aboard a moving craft the problem is complicated somewhat by the fact that time of occurrence depends upon position of the craft, and vice versa. At ship speeds, it is generally sufficiently accurate to make an approximate mental solution, and use the position of the vessel at this time to make a more accurate solution. If higher accuracy is required, the position at the time indicated in the second solution can be used for a third solution. If desired, this process can be repeated until the same answer is obtained from two consecutive solutions. However, it is generally sufficient to alter the first solution by 1^m for each 15′ of longitude that the position of the craft differs from that used in the solution, adding if west of the estimated position, and subtracting if east of it. In applying this rule, use both longitudes to the nearest 15′. The first solution is known as the first estimate; the second solution is the second estimate.

Latitude by Meridian Transit

732. Meridian altitudes.—The latitude of a place on the surface of the earth, being its angular distance from the equator, is measured by an arc of the meridian between the zenith and the equator, and hence is equal to the declination of the zenith; therefore, if the zenith distance of any heavenly body when on the meridian be known, together with the declination of the body, the latitude can be found.

Figure 732a shows the celestial sphere surrounding the earth: P_nMP_s is the upper branch of a celestial meridian and LL′ a portion of the corresponding geographic meridian. The declination of a body at M (arc QM) is numerically equal to the latitude of its geographical position at GP. The zenith distance of a body is equivalent to the distance on earth between the geographical position of the body and the position of the observer. In figure 732a the zenith distance of M is 30° and its declination is 20°N. If the body is on the meridian, the GP is also on the meridian. Since P_n, Z, and M are all on the celestial meridian, the navigational triangle flattens out to a line. The observer is 30° *north* of the GP (L 50°N) if the body is seen to bear south, or 30° *south* of the GP (L′ 10°S) if the body is seen to bear *north*. The navigator knows whether the GP is north or south, because it is the same as the direction he faces when making his observation.

In the diagram on the plane of the celestial meridian shown in figure 732b, M is the position of a celestial body north of the equator but south of the zenith; QM is the declination of the body; SM is the altitude (h); and MZ is the zenith distance (z).

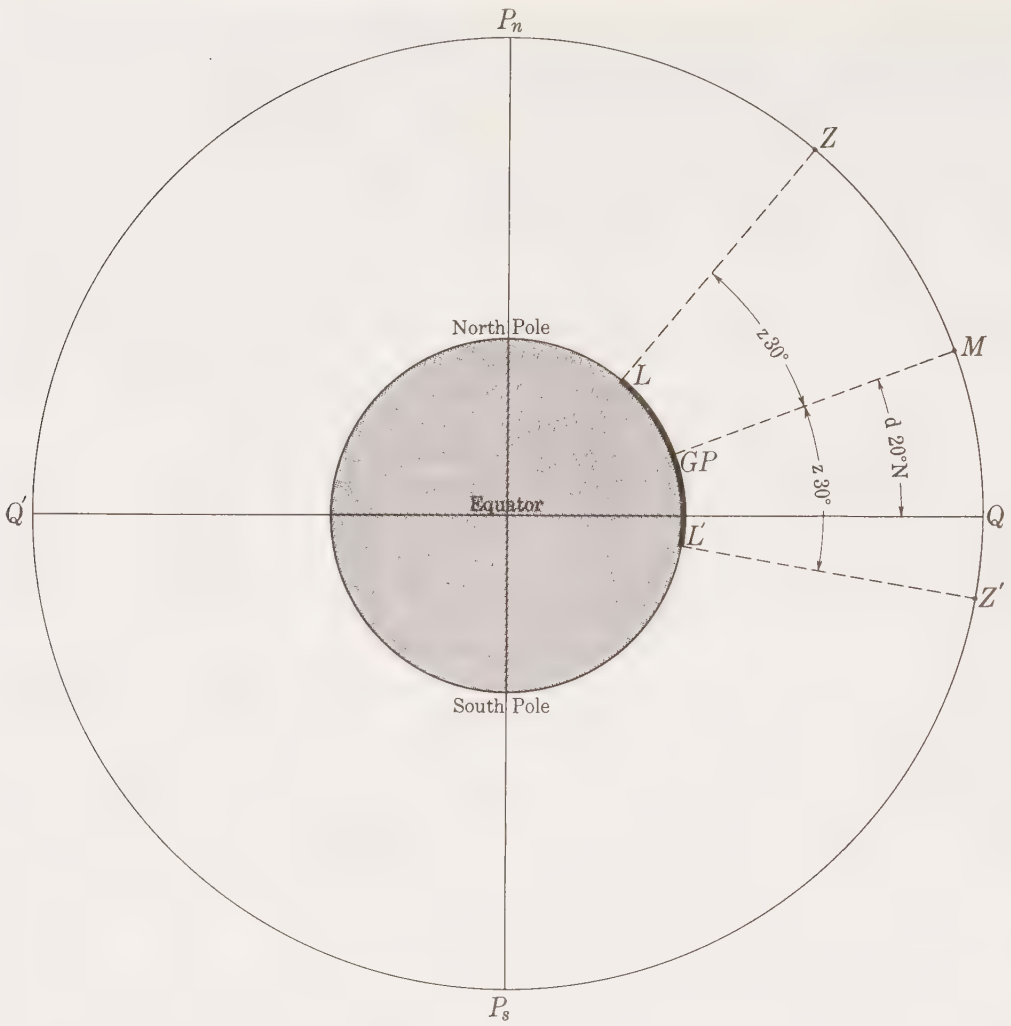

FIGURE 732a.—Body on celestial meridian.

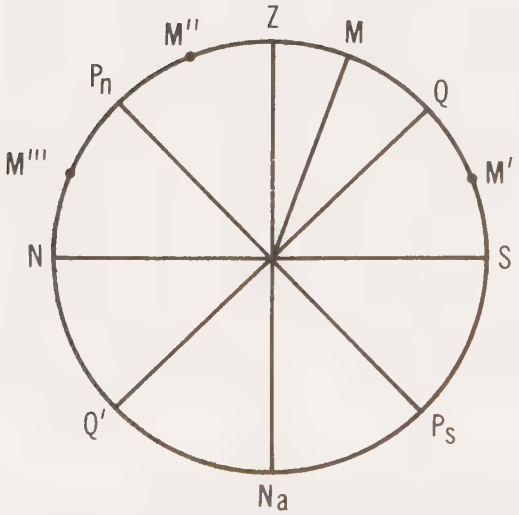

FIGURE 732b.—Diagram on the plane of the celestial meridian.

From the diagram:

$$QZ=QM+MZ, \text{ or}$$
$$L=d+z. \qquad (19)$$

With attention to the direction of the GP and the name of the declination, the above equation may be considered general for any position of the body at upper transit, as M, M′, M″.

When the body is below the pole, as at M‴—that is, at its lower transit—the same formula may be used by substituting 180°−d for d. Another solution is given in this case by observing that:

$$NP_n=P_nM'''+NM''', \text{ or}$$
$$L=p+h. \qquad (20)$$

By drawing that half of the diagram on the plane of the celestial meridian containing the zenith, the proper combination of zenith distance and declination is made obvious, as shown in the following examples:

Example 1.—The navigator observes the sun on the meridian, bearing south. The declination of the sun is 10°00′.0N; the corrected sextant altitude (Ho) is 60°00′.0.

Required.—The latitude.

Solution.— L=z+d.

	90°00′.0
Ho	60°00′.0
z	30°00′.0
d	10°00′.0N
L	40°00′.0N

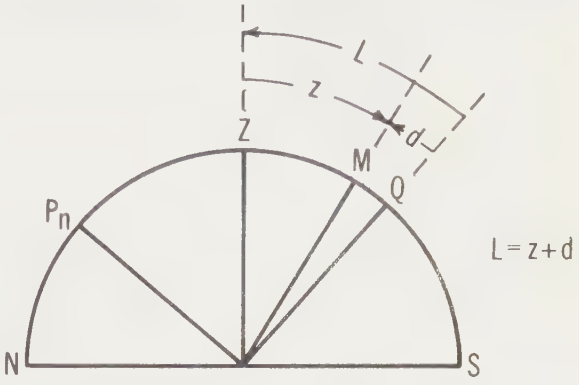

FIGURE 732c.—Meridian altitude diagram.

Example 2.—The navigator observes the sun on the meridian, bearing south. The declination of the sun is 10°00′.0S; the corrected sextant altitude (Ho) is 65°00′.0.

Required.—The latitude.

Solution.— L=z−d.

	90°00′.0
Ho	65°00′.0
z	25°00′.0
d	10°00′.0S
L	15°00′.0N

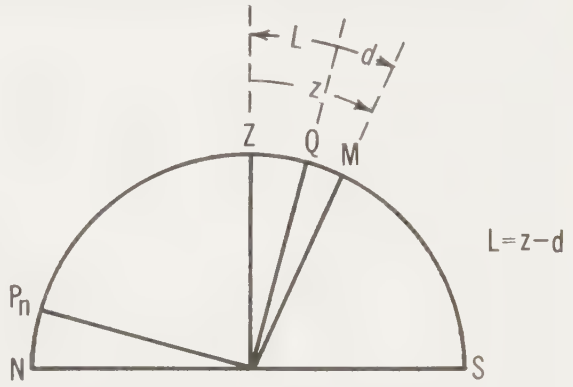

FIGURE 732d.—Meridian altitude diagram.

Example 3.—The navigator observes the sun on the meridian, bearing north. The declination of the sun is 20°00′.0S; the corrected sextant altitude (Ho) is 60°00′.0.

Required.—The latitude.

Solution.— L=z+d.

	90°00′.0
Ho	60°00′.0
z	30°00′.0
d	20°00′.0S
L	50°00′.0S

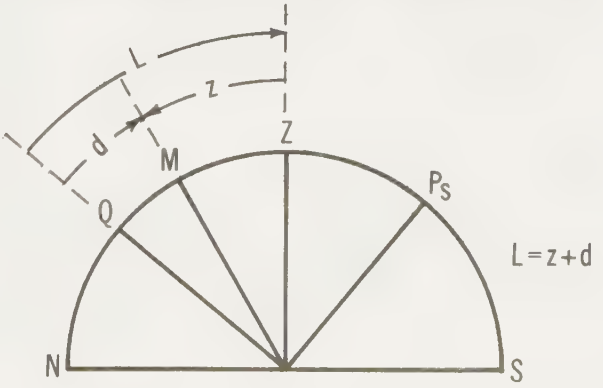

FIGURE 732e.—Meridian altitude diagram.

Example 4.—The navigator observes the sun on the meridian, bearing north. The declination of the sun is 23°00′.0N; the corrected sextant altitude (Ho) is 72°00′.0.

Required.—The latitude.

Solution.— L=d−z.

	90°00′.0
Ho	72°00′.0
z	18°00′.0
d	23°00′.0N
L	5°00′.0N

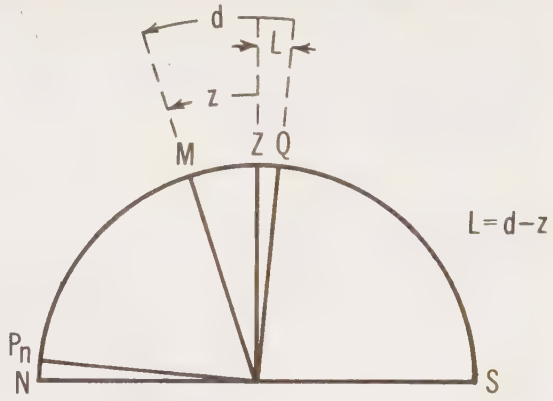

FIGURE 732f.—Meridian altitude diagram.

Example 5.—In the vicinity of the equator, the navigator observes the sun on the meridian, bearing north. The declination of the sun is 22°05′.0N; the corrected sextant altitude (Ho) is 67°45′.0.

Required.—The latitude.

Solution.— L=z−d.

	90°00′.0
Ho	67°45′.0
z	22°15′.0
d	22°05′.0N
L	0°10′.0S

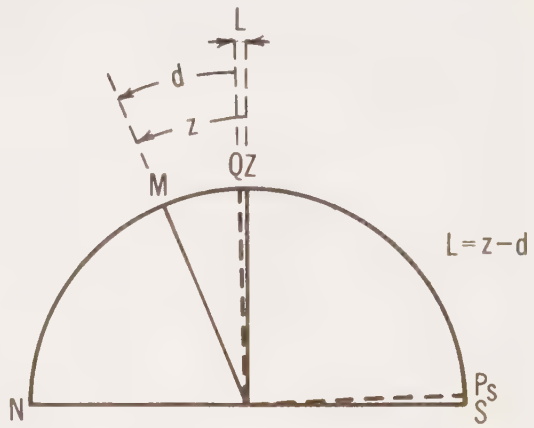

FIGURE 732g.—Meridian transit in the vicinity of the equator.

Example 6.—The navigator in high northern latitudes observes the sun on the celestial meridian, bearing north. The declination of the sun is 18°46′.0N; the corrected sextant altitude (Ho) is 6°22′.0.

Required.—The latitude.

Solution.— L=(180°−d)−z, or
L=p+h.

	90°00′.0
Ho	6°22′.0
z	83°38′.0
180°−d	161°14′.0N
L	77°36′.0N

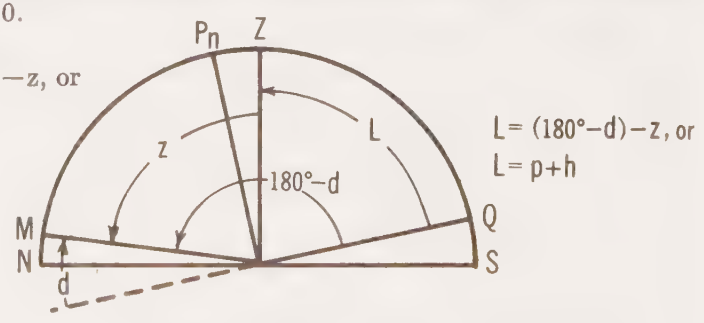

FIGURE 732h.—Meridian altitude at lower transit.

Since the sun's GP is 83°38′.0 north of the observer in high northern latitudes, the GP is beyond the pole, or on the *lower branch* of the observer's meridian.

If an observation is made near but not exactly at meridian transit, it can be solved as a meridian altitude, with one modification. Enter table 29 with the approximate latitude of the observer and the declination of the body, and take out the **altitude factor** (*a*). This is the difference between meridian altitude and the altitude one minute of time later (or earlier). Next, enter table 30 with the altitude factor and the difference of time between meridian transit and the time of observation, and take out the correction. *Add* this value to Ho if near upper transit, or *subtract* it from Ho if near lower transit. Then proceed as for a meridian altitude, remembering that the value obtained is the latitude at the time of observation, not at the time of meridian transit. This method should not be used beyond the limits of table 30 unless reduced accuracy is acceptable. This process is called **reduction to the meridian,** the altitude before adjustment an **ex-meridian altitude,** and the observation an **ex-meridian observation.** It requires knowledge of the meridian angle, which depends upon knowledge of longitude.

733. Finding time of meridian transit.—If a meridian altitude is to be observed other than by chance, a knowledge of the time of transit of the body across the meridian is needed.

On a slow-moving vessel, or one traveling approximately east or west, the time need not be known with great accuracy. The right-hand daily page of the *Nautical Almanac* gives the GMT of transit of the sun and moon across the Greenwich meridian (approximately LMT of transit across the local meridian) under the heading "Mer. Pass." In the case of the moon, an interpolation should be made for longitude. This is performed in the same manner as finding the LMT of moonrise and moonset (art. 730). In the case of planets, the tabulated accuracy is normally sufficient without interpolation. The time of transit of the navigational planets is given at the lower right-hand corner of each left-hand daily page of the *Nautical Almanac*. The tabulated values are for the middle day of the page. These times are the GMT of transit across the Greenwich meridian, but are approximately correct for the LMT of transit across the local meridian. Observations are started several minutes in advance and continued until the altitude reaches a maximum and starts to decrease (a minimum and starts to increase for lower transit). The greatest altitude occurs at upper transit (and the least at lower transit). This method is not reliable if there is a large northerly or southerly component of the vessel's motion, because the altitude at meridian transit changes slowly, particularly at low altitudes. At this time the change due to the vessel's motion may be considerably greater than that due to apparent motion of the body (rotation of the earth), so that the highest altitude occurs several minutes before or after meridian transit.

If the moment at which the azimuth is 000° or 180° can be determined accurately, the observation can be made at this time. However, this generally does not provide a high order of accuracy.

If the longitude is known with sufficient accuracy, the time of transit can be computed. A number of methods of computation have been devised, but perhaps the simplest is to consider the GHA of the body equal to the longitude if west, or 360°−λ if east, and find the time at which this occurs.

Example 1.—Find the zone time of meridian transit of the sun at longitude 156° 44′.2W on May 31, 1975.

Solution.—

	May 31	
λ	156°44′.2W	
GHA	156°44′.2	
22^h	150°36′.1	
24^m32^s	6°08′.1	
GMT	$22^h24^m32^s$	May 31
ZD	(+)10	(rev.)
ZT	$12^h24^m32^s$	

This solution is the reverse of finding GHA. The largest tabulated value of GHA that does not exceed the desired GHA is found in the tabulation for the day, and recorded, with its time. The difference between this value and the desired GHA is then used to enter the "Increments and Corrections" table. The time interval corresponding to this value is added to the time taken from the daily page. If there is a *v* correction, it is subtracted from the GHA difference before the time interval is determined. The GMT can be converted to any other kind of time desired. If the Greenwich date differs from the local date at the time of transit (for the sun this can occur only near the 180th meridian), a second solution may be needed. This possibility can often be avoided by making an approximate mental solution in advance. As the basis for this approximate solution, it is convenient to remember that the GMT of Greenwich transit (GHA 0°) is about the same as the LMT of local transit. To find the time of transit of a star, subtract its SHA from the desired GHA to find the desired GHA ♈. Determine the time corresponding to GHA ♈, as explained above for the sun.

Aboard a moving vessel, the longitude at transit usually depends upon the time of transit. An approximate mental solution may provide a time sufficiently close. In the absence of better information, use ZT 1200 for the sun. Find the time of transit for the position at this time, and then make an adjustment, if necessary, for the sun between 1200 and the time found by computation. This adjustment is equal to four seconds for each minute of longitude involved. If the ship is *west* of the 1200 position at the computed time of transit, *add* the correction; and if *east*, *subtract* it. The result is the **first estimate** of the zone time of **local apparent noon** (**LAN**) or of meridian transit. For high accuracy a second adjustment may occasionally be needed, but this is seldom justified because of the uncertainty of the vessel's position. If the second adjustment is made, the result is the **second estimate.**

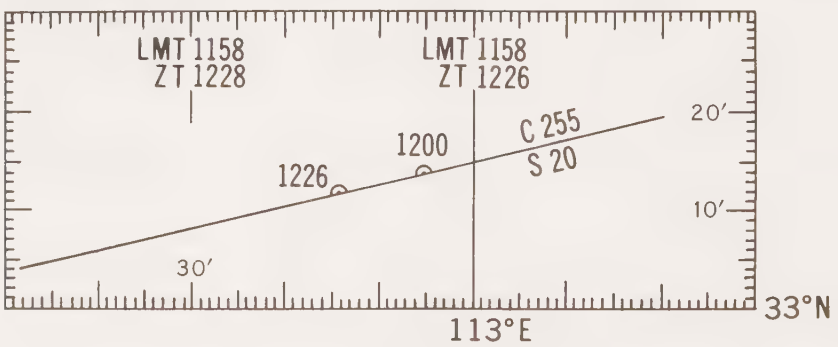

FIGURE 733.—Time of meridian passage.

The time of transit of the sun can also be found by means of apparent time (art. 611). Meridian transit occurs at LAT $12^h00^m00^s$. This can be converted to any other kind of time desired.

Example 2.—Find the zone time of meridian transit of the sun as observed aboard a ship steaming at 20 knots on course 255° on May 31, 1975, using the positional data given in figure 733.

Solution.—

	May 31	
	360°00′.0	
λ	112°55′.0E	
GHA	247°05′.0	
4^h	240°37′.7	
25^m49^s	6°27′.3	
GMT	$4^h25^m49^s$	May 31
ZD(−)	8	(rev.)
ZT	$12^h25^m49^s$	
dλ	(+) 0^m36^s	
ZT	$12^h26^m25^s$	(first estimate)

The second estimate of the zone time of meridian transit is found by plotting the DR position for the first estimate of the zone time of transit and then applying the dλ between this DR and the 1200 DR to the time found by computation.

ZT	$12^h25^m49^s$	
dλ	(+)0^m37^s	
ZT	$12^h26^m26^s$	(second estimate)

As shown in figure 733, the zone times of meridian transit are noted on several successive meridians. This is accomplished by extracting the LMT of meridian transit from the daily page of the *Nautical Almanac* and converting this time to the zone time for each meridian. The time when the ship and the sun are on the same meridian can then be obtained by inspection to within approximately one-half minute.

Polaris

734. Latitude by Polaris.—Another special method of finding latitude, available in most of the northern hemisphere, utilizes the fact that Polaris is less than 1° from the north celestial pole. As indicated in article 507, the altitude of the elevated pole above the celestial horizon is equal to the latitude. Since Polaris is never far from the pole, its observed altitude (Ho), with suitable correction, is the latitude.

The nature of this correction as tabulated in the *Air Almanac* is suggested by inspection of figure 734b in which the circle represents the path of Polaris around the north celestial pole (P_n), as seen by an observer on earth looking along the axis P_sP_n (fig. 734a). The line *ab* represents a small portion of the observer's meridian. Polaris is at upper transit at *a* and at lower transit at *b*. This is also shown in figure 734b, to larger scale. Latitude is equal to the altitude *minus* the polar distance (p) when Polaris is at *a* and *plus* the polar distance when it is at *b*. When the star is at any point *c*, the Polaris correction is polar distance times the cosine of the local hour angle (corr.$=p$ cos LHA). Thus, the correction is a function of LHA of the star, and hence also of

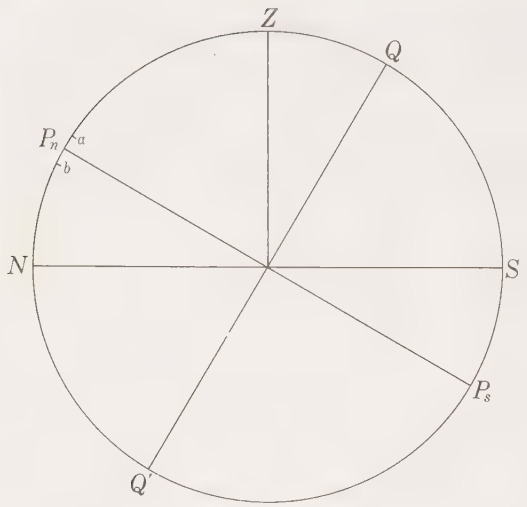

FIGURE 734a.—Latitude is equal to the (1) declination of the zenith and (2) the altitude of the elevated pole. Compare with figure 734b.

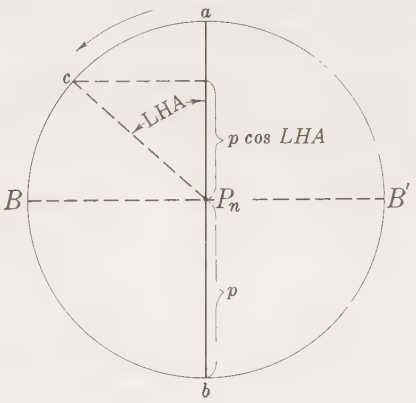

FIGURE 734b.—The correction is $(-)aPn$ when Polaris is at a and $(+)bPn$ when at b. At any point c the correction is $p$cosLHA. At B or B' the correction is zero.

LHA ♈, insofar as the difference between these quantities (the SHA) can be considered constant.

Although the above method usually provides sufficient accuracy for air navigation, a higher degree of accuracy may be obtained by use of Polaris correction tables included in the *Nautical Almanac*. These tables are based on the following formula:

Latitude—corrected sextant altitude $= -p \cos h + \frac{1}{2} p \sin p \sin^2 h \tan$ (latitude),

where p = polar distance of *Polaris* = 90° − Dec.
h = local hour angle of *Polaris* = LHA Aries + SHA.

The value a_0, which is a function of LHA Aries only, is the value of both terms of the above formula calculated for mean values of the SHA and Dec. of Polaris, for a mean latitude of 50°, and adjusted by the addition of a constant (58′.8). The value a_1, which is a function of LHA Aries and latitude, is the excess of the value of the second term over its mean value for latitude 50°, increased by a constant (0′.6) to make it always positive. The value a_2, which is a function of LHA Aries and date, is the correction to the first term for the variation of Polaris from its adopted mean position; it is increased by a constant (0′.6) to make it positive. The sum of the added constants is 1°, so that:

Latitude = corrected sextant altitude $- 1° + a_0 + a_1 + a_2$.

The table at the top of each Polaris correction page is entered with LHA Aries, and the first correction (a_0) is taken out by single interpolation. The second and third corrections (a_1 and a_2, respectively) are taken from the double entry tables without interpolation, using the LHA Aries column with the latitude for the second correction and with the month for the third correction.

Example 1.—During morning twilight on June 2, 1975, the 0525 DR position of a ship is lat. 15°43′.6N, long. 110°07′.3W. At watch time $5^h24^m49^s$ AM the navigator observes Polaris with a marine sextant having an IC of (−)3′.0, from a height of eye of 44 feet. The watch is 23^s slow on zone time. The hs is 16°24′.0.

Required.—The latitude.

Solution.—

Ho	16°11′.3

Since LHA ♈ is an entering value in all three correction tables, and since this is affected by the longitude, other observations, if available, should be solved and plotted first, to obtain a good longitude for the Polaris solution. For greater accuracy, particularly in higher latitudes, and especially if considerable doubt exists as to the longitude, it is good practice to find the azimuth of Polaris and draw the line of position perpendicular to it, through the point defined by the latitude found in the computation and the longitude used in the solution. The azimuth at various latitudes to 65°N is given below the Polaris corrections. This table can be extrapolated to higher latitudes, but Polaris would not ordinarily be used much beyond latitude 65°. In the example given above the azimuth is 000°.8.

The *Air Almanac* provides only the first correction, which it designates *Q*.

Polaris observations can be solved like those of other celestial bodies, using the declination and SHA given in the tabulation near the back of the *Nautical Almanac*.

The Polaris correction table in the *Air Almanac* lists the correction *Q* to be applied to the sextant altitude of Polaris to give the latitude of the observer. The correction is given in a critical table, with argument LHA Aries (♈) obtained from the daily pages. The effect of refraction is not included and so the sextant altitude must be fully corrected before use.

Example 2.—On 1 June 1975 at GMT $02^h53^m32^s$ in longitude 49°18′W. the corrected sextant altitude of Polaris is 54°46′.

Required.—The latitude.

Solution.—

Latitude	55°30′

CHAPTER VIII

SEXTANT ALTITUDE CORRECTIONS

801. Need for correction.—Altitudes of celestial bodies, obtained aboard ship for the purpose of establishing lines of position, are normally measured by a hand-held **sextant,** described in volume I. The uncorrected reading of a sextant after such an operation is called **sextant altitude** (**hs**). If the sextant is in proper adjustment, certain sources of error are eliminated, as explained in volume I. There remains, however, a number of sources of error over which the observer has little or no control. For each of these he applies a correction. When all of these **sextant altitude corrections** have been applied, the value obtained is the altitude of the center of the celestial body above the celestial horizon, for an observer at the center of the earth. This value, called **observed altitude** (**Ho**), is compared with the **computed altitude** (**Hc**) to find the **altitude intercept** (*a*) used in establishing a line of position as explained in chapter IX.

Articles 802–829 describe the various corrections. For highly accurate results, all of these are needed to the greatest accuracy obtainable. The needs of ordinary practical navigation, however, make no such exacting requirements, and in the course of his usual day's work at sea, the navigator has relatively few corrections to apply, from conveniently-arranged tables readily accessible to him. The detailed information in articles 802–829 is given to (1) provide the basis for a better understanding of the problem, (2) furnish the information needed for evaluation of results, and (3) provide a source of reference material beyond that given in the usual navigation text.

802. Instrument correction (**I**) is the combined correction for nonadjustable errors (prismatic error, graduation error, and centering error) of the sextant, as explained in volume I. Usually, this correction is determined by the manufacturer, and recorded on a card attached to the inside of the top of the sextant box. It varies with the angle, may be either positive or negative, and is applied to all angles measured by that instrument. For a well-made instrument, the maximum value is so small that this correction can be ignored for all except the most accurate work. Normally, instrument error of artificial-horizon sextants is so small, considering the precision to which angles can be measured by such instruments, that no correction is provided.

803. Index correction (**IC**), due primarily to lack of parallelism of the horizon glass and index mirror at zero reading, is discussed in volume I. Until the adjustment is disturbed, the index correction remains constant for all angles, and is applicable to all angles measured by the instrument. It may be either positive or negative. Normally, artificial-horizon sextants do not have index corrections.

804. Personal correction (**PC**) is numerically the same as personal error (volume I), but of opposite sign, either positive or negative. If experience indicates the need for such a correction, it should be made to altitudes of the bodies to which it applies. However, the observer should be sensitive to changes in its value. Unless the observer has sufficient evidence to be sure of the existence and relative constancy of a personal error, no correction should be applied.

805. Dip (**D**) of the horizon is the angle by which the visible horizon (art. 505) differs from the horizontal at the eye of the observer (the sensible horizon, art. 505). Thus, it applies only when the visible horizon is used as a reference, and not when an

artificial horizon, either internal or external to the sextant, is used. It applies to all celestial bodies. If the eye of the observer were at the surface of the earth, visible and sensible horizons would coincide, and there would be no dip. This is never the situation aboard ship, however, and at any height *above* the surface, the visible horizon is normally *below* the sensible horizon, as shown in figure 505a. Normally, then, an altitude measured from the visible horizon is too *great*, and the correction is *negative*. It increases with greater height of the observer's eye. Because of this, it is sometimes called **height of eye correction.**

If there were no atmospheric refraction, dip would be the angle between the horizontal at the eye of the observer, and a straight line from this point tangent to the surface of the earth.

The amount by which refraction alters dip varies with changing atmospheric conditions. Even the *average* value has not been established with certainty, and several methods of computing dip have been proposed. The values given in the critical table on the inside front cover of the *Nautical Almanac* were computed by the equation

$$D=0.97\sqrt{h},$$

where D is the dip, in minutes of arc; and h is the height of eye of the observer, in feet. Part of this table is repeated on the page facing the inside back cover. The *Air Almanac* table was computed independently by a different method, to a precision of whole minutes. The minor discrepancies thus introduced are not important in practical navigation.

The values given in the table are satisfactory for practical navigation under most conditions. An investigation by the Carnegie Institution of Washington showed that of 5,000 measurements of dip at sea, no value differed from the tabulated value by more than 2′.5, except for one difference of 10′.6. Extreme values of more than 30′ have been reported, and even values of several *degrees* have been encountered in polar regions. Greatest variations from tabulated values can be expected in calm weather, with large differences between sea and air temperatures, particularly if mirage effects are present. Irregularities in the shape of the rising or setting sun may indicate abnormal conditions. Large variations may also be present shortly after passage of a squall line, when errors of as much as 15′ have been reported. When a temperature inversion is known to exist, the tabulated dip may be too small, numerically. The effect of sea-air temperature difference is discussed in greater detail in article 814.

In the determination of height of eye, position on the ship should be considered, and also the condition of loading and trim. If an observation is made from a position differing from the usual place, the altered height of eye should not be overlooked. Momentary changes due to rolling and pitching can be neutralized, to a large extent, by making observations from a point on the center line of the vessel, at the axis of pitch.

Since variations from normal dip may be one of the principal sources of error in celestial observations, the observer should be alert to conditions affecting terrestrial refraction. Any observation taken within half an hour after passage of a squall line should be regarded as unreliable.

If dip cannot be measured, the effects of abnormal conditions can be minimized by observing three bodies differing in azimuth by about 120° (or four bodies by 90°, five bodies by 72°, etc.). If the error is constant in all directions, its effect is to increase (or possibly to decrease) the size of the closed figure formed by the lines of position without altering the position of its center. Hence, the size of the figure is not necessarily an indication of the accuracy of the fix.

If land, another ship, or other obstruction is between the observer and his horizon, an altitude can be measured by using the water line of the obstruction as a horizontal reference, if its distance from the observer is known. In this case the dip is greater than that given in the almanacs. Table 22 gives the values to be used.

Further discussion of refraction is given in article 806. When abnormal astronomical refraction occurs, abnormalities in terrestrial refraction can be expected.

806. Refraction (R).—Light, or other radiant energy, is assumed to travel in a straight line at uniform speed, if the medium in which it is traveling has uniform

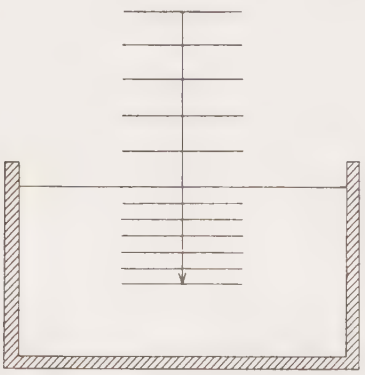

FIGURE 806a.—No refraction occurs when light enters denser medium normal to the surface.

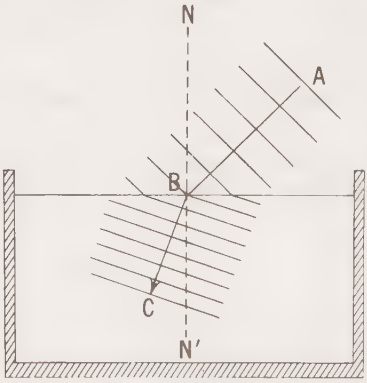

FIGURE 806b.—A ray entering a denser medium at an oblique angle is bent toward the normal.

properties. But if light enters a medium of different properties, particularly if the density is different, the speed of light changes somewhat. Light from a single point source travels outward in all directions, in an expanding sphere. At great distances, a small part of the surface of this sphere can be considered flat, and light continuing to emanate from the source can be considered similar to a series of waves, in some respects resembling the ocean waves encountered at sea. If these light "waves" enter a more dense medium, as when they pass from air into water, the speed decreases. If the light is traveling in a direction perpendicular to the surface separating the two media (in this case vertically downward), all parts of each wave front enter the new medium at the same time, and so all parts change speed together, as shown in figure 806a. But if the light enters the more dense medium at an oblique angle, as shown in figure 806b, the change in speed occurs progressively along the wave front as the different parts enter the more dense medium. This results in a change in the direction of travel, as shown. This change in direction of motion is called **refraction.** If light enters a more dense medium, it is refracted *toward* the normal (NN'), as in figure 806b. If it enters a less dense medium, it is refracted *away* from the normal, as light traveling in the opposite direction to that shown in figure 806b.

The *amount* of the change in direction is directly proportional to the angle between the direction of travel and the normal (angle ABN in figure 806b). The ratio of this angle to the similar angle after refraction takes place (angle CBN' in figure 806b) is constant, so that as one increases, the other increases at the same *rate*. Hence, the *difference* between them (the change in direction) also increases at the same rate. Therefore, if the *incident* ray (AB) is nearly parallel to the surface at which refraction takes place, relatively large amounts of refraction occur.

The amount of refraction is also directly proportional to the relative speed of travel in the two media. Various substances are compared by means of a number called the **index of refraction** (μ), which depends primarily upon the density of the substance.

In figure 806b, angle *ABN* is called the **angle of incidence** (ϕ) and angle *CBN'* the **angle of refraction** (θ). These are related by Snell's law, which states that *the sines of the angle of incidence and angle of refraction are inversely proportional to the indices of refraction of the substances in which they occur.* Thus, if μ_1 is the index of refraction of the substance in which ϕ occurs, and μ_2 is the index of refraction of the substance in which θ occurs

$$\frac{\sin \phi}{\sin \theta} = \frac{\mu_2}{\mu_1}.$$

If the index of refraction changes suddenly, as along the surface separating water and air (as shown in fig. 806b), the change in direction is equally sudden. However, if a ray of light travels through a medium of gradually changing index of refraction, its path is curved, undergoing increased refraction as the index of refraction continues to change. This is the situation in the earth's atmosphere, which generally decreases in density with increased height. The gradual change of direction occurring there is called **atmospheric refraction.** The bending of a ray of light traveling from a point on or near the surface of the earth, to the eye of the observer, is called **terrestrial refraction.** This affects dip of the horizon, as discussed in article 805. A ray of light entering the atmosphere from outside, as from a star, undergoes a similar bending called **astronomical refraction.**

The effect of astronomical refraction is to make a celestial body appear *higher* in the sky than it otherwise would, as shown in figure 806c. If a body is in the zenith, its light is not refracted, except for a very slight amount when the various layers of the atmosphere are not exactly horizontal. As the zenith distance increases, the refraction becomes greater. At an altitude of 20° it is about 2′.6; at 10°, 5′.3; at 5°, 9′.9; and at the horizon, 34′.5. A table of refraction is given on the inside front cover and facing page of the *Nautical Almanac,* in the columns headed "Stars and Planets." As height above the surface of the earth increases, light from an outside source travels through less of the atmosphere, and refraction decreases. At shipboard heights the difference is negligible, but at aircraft heights the change is a consideration. **Therefore, the refraction table given near the back of the *Air Almanac* is a double-entry table.**

FIGURE 806c.—Astronomical refraction.

The values given in the tables are for average conditions. This is called **mean refraction.** A considerable amount of research has been conducted to determine the mean values, the conditions under which values differ from the mean, and the amount of such differences. A number of different mean refraction tables have been produced. Values in the various tables differ slightly because of different assumptions, different methods of observation, and different observed results under apparently similar conditions. This last source of difference is due primarily to the fact that conditions could be determined at the position of the observer, but not at various points along the line traveled by the ray of light in passing through the atmosphere. Nevertheless, the various tables agree very well down to a minimum altitude of 2°. Below this, the refraction is erratic, and differences between values in the various tables are

not as important as differences between mean and instantaneous values. The values given in the almanac tables are in excellent agreement with those actually measured.

Because of their variability, refraction and dip (also affected by refraction) are the principal uncertainties in the accuracy of celestial observations of a careful observer. As a result of this uncertainty, navigators formerly avoided all observations below some arbitrary altitude, usually 15°. While this is still good practice if higher bodies are available, the growing knowledge of atmospheric refraction has increased the confidence with which navigators can use low-altitude sights. There is little reason for lack of confidence in sights as low as 5°. Below this, other available corrections should be applied (art. 828). If altitudes below 2° are used, larger probable errors should be anticipated, even with the use of **additional** corrections. Generally, the error in tabulated refraction should not exceed two or three minutes, even at the horizon. However, a knowledge of conditions affecting refraction is helpful in determining the confidence to be placed in such observations. Since refraction elevates both the celestial body and the visible horizon, the error due to abnormal refraction is minimized if the visible horizon is used as a reference.

The atmosphere contains many irregularities which are erratic in their influence upon refraction. Normally, the navigator has not the information needed to correct for such conditions, but only to recognize their existence. He must recognize that those observations made within half an hour after passage of a squall line might be considerably in error. The passage of any front might have a similar effect. A temperature inversion (volume I) may upset normal refraction. Abnormal values may be expected when there is a large difference between the temperature of the sea and air. With an absence of wind, the air tends to form in layers. When this condition becomes extreme, mirage effects occur. Sometimes the rising or setting sun or moon appears distorted. Multiple horizons may appear, and other ships or islands may seem to float a short distance above the water. Under any such conditions large errors in refraction might be encountered.

Conditions causing abnormal refraction can be expected to occur with considerable frequency in the vicinity of the Grand Banks, along the west coast of Africa from Mogador to Cap Blanc and from the Congo to the Cape of Good Hope, in the Red Sea and the Persian Gulf, and over ice-free water in polar regions. Abnormal refraction may be encountered when offshore winds blow from high, snow-covered mountains to nearby tropical seas, as along the west coast of South America; where cold water from large rivers such as the Mississippi flows into warm sea water; when a strong current flows past a bay or coast, causing colder water to be drawn to the surface, as in the Bay of Rio de Janeiro and Santos, and along the Atlantic coast of Africa between Cape Palmas and Cape Three Points during the time of the southwest monsoon; and along the east coast of Africa in the vicinity of Capo Guardafui during the summer. In the temperate zones abnormal refraction is most common during the spring and summer.

Of the more systematic errors which affect refraction, two can be evaluated, and corrections applied. These are for air temperature (art. 807) and atmospheric pressure (art. 808). However, these corrections are based upon assumed standard *gradients* (changes) with height. Temperature gradients are known to vary with type of weather, time of day, season, etc., as well as in a more irregular manner. The various layers of the atmosphere are assumed to be horizontal to the surface, but this is not always the situation. When they tilt, refraction changes. No correction for this cause is available.

Humidity has a relatively slight effect on refraction. In completely dry air, astronomical refraction at the horizon (sometimes called **horizontal refraction**) is perhaps 0′.1 *greater* than the tabulated value. In very moist air, sometimes encountered in the tropics, the maximum refraction might possibly *decrease* by as much as 0′.2.

Wind speed is believed to have some effect upon refraction and dip. Apparently, refraction increases as wind speed becomes greater, the amount of change increasing in direct proportion to the *square* of the wind speed. At 20 knots the change is believed to be about 0′.1 at the horizon, and 0″.15 at altitude 2°. At 30 knots these values are approximately doubled.

Latitude has a slight effect upon refraction because of the decrease in the radius of the earth and the increase of gravity as latitude increases. Both radius and gravity affect density of the atmosphere, and hence refraction. Because of this, mean horizontal refraction is decreased about 0′.2 to 0′.3 at the equator, and increased about an equal amount at the poles. For normal altitudes the change is negligible.

Azimuth may have an effect at some locations. The reason for this is not entirely clear, but is believed to be due to a somewhat permanent tilt of certain atmospheric layers. A series of observations at a location in Germany indicated a difference of as much as 0′.5 between northerly and southerly observations of 0° altitude. At altitude 2° the difference was only 3″. The navigator normally does not have information required to apply such a correction, nor is it of navigational significance at normal altitudes. However, differences should be anticipated when the appearance of the horizon varies with azimuth, or large sea temperature differences exist within a few miles, as near the edge of the Gulf Stream. The same might be true near land, particularly in the tropics.

Dispersion of light of various colors results in light from blue stars being refracted more than light from red stars. At the horizon the maximum correction would be about 2″ for blue stars, and 8″ for red stars. At 5° the amount would be less than one-third these values.

Errors in the tables due to incorrect assumptions are probably too small to be of practical interest to the navigator. If increased knowledge indicates errors exist in the tables, corrected values will undoubtedly be provided.

Since refraction causes celestial bodies to appear elevated in the sky, they are above the horizon longer than they otherwise would be. The mean diameter of the sun and moon are each about 32′, and horizontal refraction is 34′.5. Therefore, the entire sun or moon is actually below the visible horizon when the lower limb appears tangent to the horizon. The effect of dip is to further increase the time above the horizon. Near the horizon the sun and moon appear flattened because of the rapid change of refraction with altitude, the lower limb being raised by refraction to a greater extent than the upper limb.

As a correction to sextant altitudes, refraction is negative because it causes the measured altitude to be too *great*. It *decreases* with increased altitude, and applies to all celestial bodies, regardless of sextant or horizon used.

807. Air temperature correction (T).—The *Nautical Almanac* refraction table is based upon an air temperature of 50° F (10° C) at the surface of the earth. At other temperatures the refraction differs somewhat, becoming greater at lower temperatures, and less at higher temperatures. Table 23 provides the correction to be applied to the altitude to correct for this condition. If preferred, this correction can be applied with *reversed sign* to the refraction from the almanac, and a single refraction applied to the altitude. A combined correction for nonstandard air temperature and nonstandard atmospheric pressure (art. 808) is given on page A4 of the *Nautical Almanac*. The correction for air temperature varies with the temperature of the air and the altitude of the celestial body, and applies to all celestial bodies, regardless of the method of observation. However, except for extreme temperatures or low altitudes, this correction is not usually applied unless results of unusual accuracy are desired.

808. Atmospheric pressure correction (B).—The *Nautical Almanac* refraction table is based upon an atmospheric pressure of 29.83 inches of mercury (1010 millibars)

at sea level. At other pressures the refraction differs, becoming greater as pressure increases, and smaller as it decreases. Table 24 provides the correction to be applied to the altitude for this condition. A combined correction for nonstandard air temperature (art. 807) and nonstandard atmospheric pressure is given on page A4 of the *Nautical Almanac*. If the correction is to be applied to the refraction, reverse the sign. This correction varies with atmospheric pressure and altitude of the celestial body, and is applicable to all celestial bodies, regardless of the method of observation. However, except for extreme pressures or low altitudes, this correction is not usually applied unless results of unusual accuracy are desired.

809. Irradiation correction (J).—When a bright surface is observed adjacent to a darker one, a physiological effect in the eye causes the brighter area to appear to be larger than is actually the case; conversely, the darker area appears smaller. This is called **irradiation.** Thus, since the sun is considerably brighter than the sky background, the sun appears larger than it really is; and when the sky is considerably brighter than the water, the horizon appears slightly depressed. The effects on the horizon and lower limb of the sun are in the same direction and tend to cancel each other while the effect on the upper limb of the sun is in the opposite direction to that on the horizon and tends to magnify the effect.

From 1958–1970 a correction of 1′.2 was included in the *Nautical Almanac* data for the upper limb of the sun as an average correction for the effect of irradiation. Recent investigations have not supported that average value and have revealed that the magnitude of the effect depends on the individual observer, the size of the ocular, the altitude of the sun, and other variables. In summary, the accuracy of observations of the limb of the sun at low altitudes may be affected systematically by irradiation, but the size of the correction is so dependent upon the variables enumerated above that it is not feasible to include an average correction in the tables.

810. Semidiameter (SD) of a celestial body is half the angle, at the observer's eye, subtended by the visible disk of the body. The position of the lower or upper limb of the sun or moon with respect to the visible horizon can be judged with greater precision than that of the center of the body. For this reason it is customary, when using a marine sextant and the visible horizon, to observe one of the limbs of these two bodies, and apply a correction for semidiameter. Normally, the lower limb is used if it is visible. In the case of a gibbous or crescent moon, however, only the upper limb may be available. Semidiameter is shown in figure 812.

The semidiameter of the sun varies from a little less than 15′.8 early in July, when the earth is at its greatest distance from the sun, to nearly 16′.3 early in January, when the earth is nearest the sun. In the *Nautical Almanac* the semidiameter of the sun at GMT 12^h on the middle day of each page opening of the daily page section is given to the nearest 0′.1 at the bottom of the sun's GHA column. The altitude correction tables of the sun, given on the inside front cover and facing page, are divided into two parts, to be used during different periods of the year. The mean semidiameter of each period is included in the tables of both upper and lower limb corrections. The semidiameter each day is listed to the nearest 0″.01 in the *American Ephemeris and Nautical Almanac*. In the *Air Almanac* the semidiameter to the nearest 0′.1 is given near the lower right-hand corner of each daily page.

The moon undergoes a similar change in semidiameter as its distance from the earth varies. However, because of the greater eccentricity of the moon's orbit than that of earth, the variation in semidiameter is also greater, varying between about 14′.7 and 16′.8. The variation is more rapid, partly because of the greater spread of values, but principally because the moon completes its revolution in approximately one month, while the earth makes one revolution per year. In the *Nautical Almanac*,

semidiameter of the moon at 12^h each day is given to the nearest 0′.1 at the bottom of the moon data columns. The correction for semidiameter of the moon is included in the corrections given on the inside back cover and facing page. In the *Air Almanac*, semidiameter is given to the nearest whole minute, being shown on the daily pages, immediately below the value for the sun. The semidiameter at intervals of half a day is given to the nearest 0′.01 in the *American Ephemeris and Nautical Almanac*.

The navigational planets have small semidiameters. For Venus it varies between about 5″ and 32″; for Mars, 2″.7 to 12″.6; for Jupiter, 16″ to 25″; and for Saturn, 7″ to 10″. The value for any date is given in the *American Ephemeris and Nautical Almanac*, but not in the *Nautical Almanac* or *Air Almanac* because the apparent *centers* of these bodies are customarily observed.

Stars have no measurable semidiameter.

The computed altitude of a body refers to the *center* of that body, since the coordinates listed in the almanacs are for the center. If the *lower* limb is observed, the sextant altitude is *less* than the altitude of the center of the body, and hence the correction is *positive*. If the *upper* limb is observed, the correction is *negative*. The correction does not apply when the center of the body is observed, which is usually the case when an artificial-horizon sextant is used. With a marine sextant and either the natural or an artificial horizon, semidiameter is customarily applied to observations of the sun and moon, but not other celestial bodies.

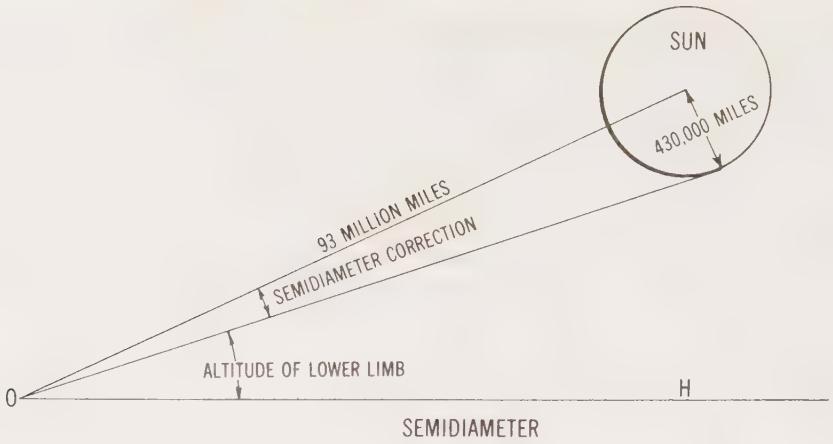

811. Phase correction (**F**).—Because of phase (fig. 812), the actual centers of planets and the moon may differ somewhat from the apparent centers. Average corrections for this difference are included in the additional corrections for Venus and Mars given on the inside front cover of the *Nautical Almanac*. They should be applied only when these bodies are observed during twilight. At other times the magnitude and even the sign of the correction might differ from those tabulated, because of a different relationship between the body and the horizon. The phase correction for navigational planets other than Venus and Mars is too small to be significant.

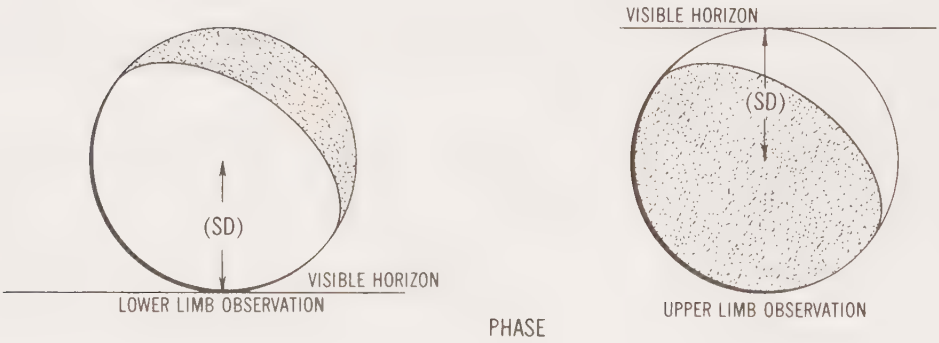

A phase correction may apply to observations of the moon if the apparent center of the body is observed, as with an artificial-horizon sextant. However, no provision is made for a correction in this case; the need for it can be avoided by observing one of the limbs of the body.

Phase correction does not apply to observations of the sun or stars.

812. Augmentation (**A**).—As indicated in article 810, semidiameter changes with distance of the celestial body from the observer, becoming greater as the distance decreases. The semidiameter given in the ephemeris and used in the almanacs is for a fictitious observer at the center of the earth. If the celestial body is on the actual observer's horizon, its distance is approximately the same as from the center of the earth; but if the body is in the zenith, its distance is less by about the radius of the earth (fig. 812). Therefore, the semidiameter *increases* as the altitude becomes greater. This increase is called **augmentation.** For the moon, the augmentation from horizon to zenith is about 0′.3 at the mean distance of the moon. At perigee it is about 2″ greater, and at apogee about 2″ less. Augmentation of the sun from horizon to zenith is about 1/24 of one second of arc. For planets it is correspondingly small, varying with the positions of the planets and the earth in their orbits. At any altitude the augmentation is equal to the sine of the altitude times the value at the zenith.

Augmentation increases the size of the semidiameter correction, whether positive or negative. It is included in the moon correction tables on the inside back cover and facing page of the *Nautical Almanac*. It is not included in the correction tables of other bodies or in the *Air Almanac* tables.

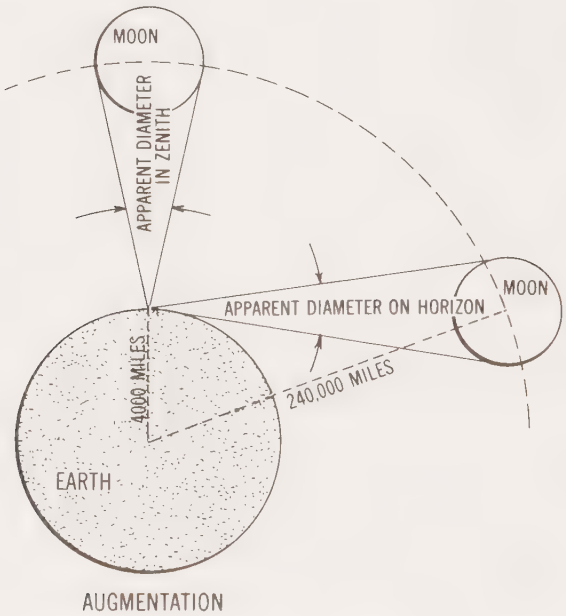

FIGURE 812.—Semidiameter, phase, and augmentation.

813. Parallax (**P**) is the difference in apparent position of a point as viewed from two different places. If a finger is held upright at arm's length and the right and left eyes closed alternately, the finger appears to move right and left a short distance. Similarly, if one of the nearer stars were observed from the earth and from the sun, it would appear to change slightly with respect to the background of more distant stars. This is called **heliocentric parallax** or **stellar parallax.** The nearest star has a parallax of less than 1″. Even if the value were greater, no correction to sextant altitudes would be needed, for the difference would be reflected in the tabulated position of the body.

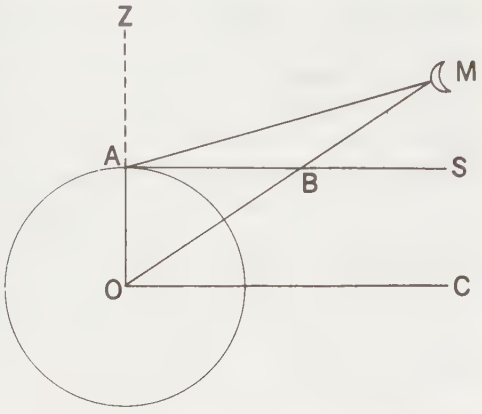

FIGURE 813.—Geocentric parallax.

However, positions of celestial bodies are given relative to the *center* of the earth, while observations are made from its surface. The difference in apparent position from these two points is called **geocentric parallax.** If a body is in the zenith, at Z in figure 813, there is virtually no parallax, for the line from the body to the center of the earth passes approximately through the observer at *A*. Suppose, however, the moon is at *M*. From *A* it appears to be along the line *AM*, while at the center of the earth it would appear to be along *OM*. The altitude at *A* would be the angle *SAM*, and that at *O* the angle *COM*. Angle *COM* is equal to angle *SBM* (art. 127), which is exterior to the triangle *ABM*, and hence equal to the sum of angles *SAM* and *AMO* (art. 128).

Since

$$\angle COM = \angle SBM = \angle SAM + \angle AMO,$$

then

$$\angle AMO = \angle COM - \angle SAM.$$

That is, the angle at the body between lines to the observer and the center of the earth is equal to the difference in altitude at the two places. Angle *AMO* is the geocentric parallax. Since it varies with altitude, it is sometimes called **parallax in altitude** (**P in A**). The maximum value for a visible body occurs when that body is on the horizon, at *S*. At this position the value is called **horizontal parallax** (**HP**).

The sine of horizontal parallax is equal to $\frac{r}{D}$, where r is the radius of the earth, and D the distance of the body from the center of the earth. Thus, the sine of the horizontal parallax is directly proportional to the radius of the earth, and inversely proportional to the distance of the body. Since the earth is an oblate spheroid, and not a sphere, the parallax varies slightly over different parts of the earth. The value at the equator, called **equatorial horizontal parallax,** is greatest, and the value at the poles, called **polar horizontal parallax,** is least. The difference is not enough to be of practical navigational significance. The parallax in altitude is equal almost exactly to the horizontal parallax times the cosine of the altitude (h). That is,

$$\text{P in A} = \text{HP} \cos \text{h}.$$

The moon, being nearest the earth, has the greatest parallax of any celestial body used for navigation. The equatorial horizontal parallax at mean distance is 57′02.″70.

As the distance of the moon varies, so does the parallax, becoming greater as the moon approaches closer to the earth, and less as it recedes, horizontal parallax varying several minutes each side of the value at mean distance. For the sun, mean equatorial horizontal parallax, called **solar parallax,** is 8″.80. Differences in position on the earth, and distance from the sun, have small effect, the maximum variation due to the latter being about 0″.15. Horizontal parallax of the planets varies considerably because of the large differences in their distances from the earth. For Venus the value varies between 5″ and 32″; for Mars, 3″ and 24″; for Jupiter, 1″ and 2″; and for Saturn, 0″.8 and 1″.0. The geocentric parallax of stars is too small to be measured, even by the most precise telescopes, since the value for the nearest star is only 0″.00003.

Daily values of horizontal parallax for the sun, moon, and planets are given in the *American Ephemeris and Nautical Almanac,* to a precision of 0″.01. In the *Nautical Almanac,* mean values for the sun are included in the two sun correction tables given on the inside front cover and facing page. Horizontal parallax of the moon is tabulated at intervals of one hour on the daily pages. This value is used to enter the lower part of the moon correction tables on the inside back cover and facing page. The additional corrections for Venus and Mars given on the inside front cover are partly for parallax. No correction is given for parallax of Jupiter and Saturn. The *Air Almanac* gives parallax corrections only for the moon. These values are given in the "Moon's P in A" column on each daily page.

Because of the geocentric parallax, a body appears too *low* in the sky. Therefore, the correction is always positive. It applies regardless of the method of observation.

814. Sea-air temperature difference correction (S).—Under normal atmospheric conditions, the temperature and pressure both decrease at standard rates with increase in height above the surface. Accordingly, the *density* of the atmosphere also decreases at a standard rate, which is uniform over the height encountered aboard ship. The effect of refraction upon dip, as given in the tables, is based upon this standard rate. Usually, the difference between standard and actual conditions is not great enough to introduce important errors in the assumption that standard conditions exist.

However, when there is a difference between sea and air temperatures at the surface, the air in contact with the sea is warmed or cooled by the sea water, upsetting the normal rate of decrease near the surface. The effect is greater as the temperature difference increases. It may extend only a few inches above the surface, or for hundreds of feet. Under extreme conditions, if the air is very much colder than the water, the surface may steam. The **frost smoke** rising from the water may obscure the horizon, and under the most severe conditions it may rise to such heights as to interfere with visibility. Celestial bodies can be seen, but altitudes cannot be measured with a marine sextant because of lack of a horizon.

Under less extreme conditions, the dip is altered, but observations may seem normal. If the water is warmer than the air, the horizon is depressed and dip is increased. Under these conditions the measured altitudes are too great. Therefore, as a correction to the *altitude,* the sea-air temperature difference correction is negative when the water is warmer than the air. When the air is warmer, the reverse is true, and the altitude correction is positive.

Various attempts have been made to establish a simple relationship between the sea-air temperature difference and the correction, but the results reported by different investigators differ considerably. This is due, in part, to difference of opinion as to the height and depth at which measurements should be made, difficulties in obtaining accurate readings near the surface, variations of temperature differences at the ship and along the line of sight to the horizon, and influence of the vessel on temperatures in its immediate vicinity. Wind, too, has a considerable effect. On a calm day, the

lower portion of the atmosphere tends to form in layers, without mixing. If there is a strong, gusty wind, turbulence in the air minimizes the effect due to temperature difference. Actually, sea temperature serves only to indicate temperature at the surface, but temperature gradient in the water may be large, as in the air. Therefore, the ideal would seem to be the measurement of *air* temperature *at the surface,* and at some greater height, since it is the abnormal **lapse rate** (decrease of air temperature with height) that produces the change in normal terrestrial refraction.

Suggested factors based upon difference between temperature of the sea and air vary from about 0′.11 per degree Fahrenheit (0′.20 per degree Celsius) to 0′.21 per degree Fahrenheit (0′.37 per degree Celsius). The average of these is about 0′.16 per degree Fahrenheit (0′.28 per degree Celsius). Thus, the correction is about one-sixth of a minute per degree Fahrenheit, or one minute for each six degrees.

This correction applies to all bodies when the sea horizon is used. However, it should be used with caution, and only under conditions which indicate that better results will be obtained if it is used. Under normal conditions, it is not used. If abnormal conditions are suspected, observations are avoided or considered of questionable reliability; or the precautions indicated in article 805 are used. If allowance for abnormal conditions is made by using an altered value of dip, as one obtained by measurement, the sea-air temperature difference correction is not used. That is, if allowance is made for abnormal dip, *either* the tabulated value of dip is altered *or* the sea-air temperature correction is applied, *but not both.*

815. The uncorrected errors.—When a body is in motion over the surface of the earth, its motion *in space* is a combination of its motion relative to the earth, and the motion of the earth. Because of the rotation of the earth, principally, the path is a curved one. As a result, there is an apparent force causing deflection to the right in the northern hemisphere and to the left in the southern hemisphere. Because of this **Coriolis force,** ocean currents set in motion by wind flow in a direction to the right (northern hemisphere) of the direction in which the wind blows. Wind, too, is deflected. Instead of blowing directly from an area of high pressure to one of low pressure, and soon neutralizing the pressure difference, it moves toward one side. The result is the characteristic circulation around highs and lows.

The liquid of the bubble chamber of a bubble sextant, and a pendulum, are similarly affected, causing them to give a false indication of the vertical (or horizontal). The same is true of an artificial horizon. The equation for the deflection is

$$Z=2'.62\ S \sin L+0'.146\ S^2 \sin C \tan L-5'.25\ SC',$$

where Z is the *Coriolis correction,* S the speed over the surface of the earth in units of *hundreds* of knots, L the latitude, C the true course angle, and C′ the rate of change of true course angle in degrees per minute. The first term, 2′.62 S sin L, corrects for motion along a great circle; the second term, 0′.146 S^2 sin C tan L, is an additional correction for the difference between motion along a rhumb line, and equivalent motion along a great circle; and the third term, 5′.25 SC′, is an additional correction for departures from the course, being negative (as shown) if the departure is right in the northern hemisphere or left in the southern hemisphere. Coriolis corrections (first term only) are given near the back of the *Air Almanac.*

Coriolis correction may be either positive or negative, and varies with speed and latitude. It applies to all bodies equally, and therefore can be applied to the altitude, the assumed position, or even as an adjustment to the plotted line of position or fix. If the AP or fix is adjusted, it is moved perpendicular to the course line, to the *right* in the northern hemisphere and to the *left* in the southern hemisphere, unless the third

term is of such magnitude and sign as to make the entire correction negative, when it is applied in the opposite direction. If the correction is applied to the altitude, the value obtained by formula is multipled by the sine of the *relative* azimuth. In the northern hemisphere, the resulting altitude correction is positive if the celestial body is on the starboard side, and negative if on the port side. In the southern hemisphere these signs are reversed. These signs assume t' at the value obtained by the formula is positive. If it is negative, all signs are reversed.

At ship speeds, the Coriolis correction is not large, unless the vessel is yawing considerably. For a ship steaming at 20 knots on a steady course of 090° at latitude 40°, the maximum Coriolis correction is 0'.3 for a celestial body which is abeam. Acceleration error due to rolling and pitching of the vessel is usually much greater than this, and is the principal reason why bubble or pendulum sextants are not often used aboard ship.

There is no Coriolis correction when the visible horizon is the horizontal reference.

If an artificial horizon-sextant with a bubble or pendulum is used, the liquid of the bubble chamber or the pendulum is affected by all accelerations of the instrument. The same is true of the free surface of the liquid of an artificial horizon. With high accelerations such as those due to rolling and pitching of a vessel, or changes of course or speed, the **acceleration error** can be very large. It is for this reason that such instruments are not customarily used aboard ship. Under normal conditions at sea the navigator does not have the information needed to compute the correction. The error is minimized by making observations at the center of roll and pitch of the ship, or averaging the values taken at both ends of a roll or pitch. Observations should not be made during a turn or when the speed is being changed. Even with these precautions the error is usually unacceptably large except with an almost flat, calm sea. The effect on the level of the sea surface due to accelerations of the earth in its rotation or revolution is considered negligible.

The correction may be either positive or negative, and applies equally to all bodies observed with a bubble or pendulum sextant.

Usually, the direction of gravity is assumed to be normal (vertical) to the spheriodal surface of the earth. This assumption is not quite correct. Irregularities in density and height of the material making up the surface crust of the earth result in slight alterations of the direction of gravity. This **deflection of the vertical** is most apparent near high mountains bordering a deep sea where an extreme value of more than 1'.1 might be encountered.

Normally, values of deflection of the vertical are not available to the navigator, and are not needed by him. In precise work, however, such values for a particular area might be furnished. The correction is negative in the direction toward which the zenith is deflected, and positive in the opposite direction. In any other direction it is equal approximately to the maximum deflection times the cosine of the angle between the given direction and the direction of maximum deflection, taking the sign of the nearest maximum deflection. It is applicable to all celestial bodies, whether the natural sea horizon or an artificial horizon is used.

Corrections for dip are based upon the assumption of a calm sea. Waves disturb this condition, causing the surface to be alternately raised and lowered. At the horizon, the troughs of waves are usually not visible. Through binoculars, irregularities in the line forming the horizon can sometimes be seen, but observations are made from the *tops* or nearly the tops of the waves.

This correction for wave height is always positive, and applies to all celestial bodies, but only if the sea horizon is used as a reference. Normally, it is not applied because of the difficulty of determining (1) wave height at the horizon, and (2) height of eye above the equivalent calm level of the sea. Better practice is usually to estimate height of eye above the wave tops, allowing for motions of the vessel, and make no correction.

The height of the sea at any place is affected by the density of the sea water, its temperature, and atmospheric pressure. Because of differences in these values, the height varies from place to place. This results in tilting of the surface of the sea, which is "downhill" from the ridge of high water to that of low water. The maximum tilt due to these causes is probably a little more than 1′.5. The wave caused by the tides also tilts the sea surface. However, on the open sea, tides are seldom more than about two and one-half feet high, and the distance from crest to trough is about 5,400 miles, or one-quarter of the great-circle distance around the earth. Under these conditions, the maximum tilting of the sea surface due to tides is about 0′.025. This may be increased somewhat by storm waves or tsunamis. In confined waters, particularly in a funnel-shaped area where tides enter from the wide end and progress up a narrowing estuary, the error may be very much greater, possibly reaching a value of half a *minute*.

The correction is positive in the direction of high water and negative in the direction of low water. Between these directions it is equal approximately to the value in these directions multiplied by the cosine of the angle between the wave axis (the line perpendicular to the wave front) and the azimuth of the body. It applies equally to all bodies when the visible horizon is used as the reference. In practice it is not applied.

816. Summary of corrections.—The essential information regarding the application of the various corrections may be tabulated as shown below. In the "Bodies" column, the symbols are: ☉, sun; ☾, moon; P, planets; ☆, stars. In the "Sextants" column, M refers to a marine sextant with visible horizon, A refers to a marine sextant with artificial horizon, and B refers to an artificial-horizon sextant. The tabulation assumes that completely accurate results are desired and that corrections are to be made in the usual manner, where they are available. Some of the entries need qualification, which may be found in the preceding articles.

Correction	*Symbol*	*Sign*	*Increases with*	*Bodies*	*Sextants*	*Source*
Instrument	I	±	changing altitude	☉, ☾, P, ☆	M, A, B	sextant box
Index	IC	±	constant	☉, ☾, P, ☆	M, A, B	measurement
Personal	PC	±	constant	☉, ☾, P, ☆	M, A, B	measurement
Dip	D	−	higher height of eye	☉, ☾, P, ☆	M	almanacs
Sea-air temp. diff.	S	±	greater temp. diff.	☉, ☾, P, ☆	M	computation
Refraction	R	−	lower altitude	☉, ☾, P, ☆	M, A, B	almanacs
Air temp.	T	±	greater diff. from 50° F	☉, ☾, P, ☆	M, A, B	almanacs, table 23
Atmospheric pressure	B	±	greater diff. from 29.83 inches of mercury	☉, ☾, P, ☆	M, A, B	*Nautical Almanac*, table 24
Irradiation	J	−		☉	M, A	
Semidiameter	SD	±	lesser dist. from earth	☉, ☾	M, A	almanacs
Phase	F	±	phase	P	M, A, B	*Nautical Almanac*
Augmentation	A	±	higher altitude	☾	M, A	*Nautical Almanac*
Parallax	P	+	lower altitude	☉, ☾, P	M, A, B	almanacs

These corrections can be considered to fall into five groups:

1. *Corrections for inaccuracies in reading.* Instrument correction, index correction*, and personal correction.

2. *Corrections for inaccuracies in reference level.* Dip* and sea-air temperature difference.

3. *Corrections for bending of ray of light from body.* Refraction*, air temperature, atmospheric pressure.

4. *Adjustment to equivalent reading at center of body.* Irradiation, semidiameter*, phase, augmentation.

5. *Adjustment to equivalent reading at center of earth.* Parallax*.

In the ordinary practice of seamen, extreme accuracy is not required, and only the principal correction of each group is applied (except that augmentation is applied for the moon). These principal corrections are indicated by asterisks. For low altitudes, additional corrections are applied, as indicated in article 827.

817. Order of applying corrections.—For purposes of ordinary navigation, sextant altitudes can be applied in any order desired, using sextant altitude for the entering argument whenever altitude is required. This practice is not strictly accurate, but for altitudes usually observed, the error thus introduced is too small to be of practical significance. When extreme accuracy is desired, however, or at low altitudes, where small changes in altitude result in significant changes in correction, the order of applying corrections is important. Corrections from the first two groups of article 816 are applied to sextant altitude (hs) to obtain **apparent (rectified) altitude (ha),** which is then used as an entering argument for obtaining corrections of the third group. For strictest accuracy, all corrections of the first three groups and, in addition, irradiation and semidiameter, should be applied before augmentation, and all other corrections before parallax.

818. Marine sextant corrections.—As shown in articles 816 and 817, all corrections except Coriolis and acceleration apply to marine sextant observations when the visible horizon is used. However, under normal conditions and when the highest accuracy is not required, it is necessary to apply only a few corrections. Several of these corrections may be combined within a single altitude correction table. In addition to corrections for index error, dip, and mean refraction, the normal altitude corrections when using the *Nautical Almanac* are: phase and parallax for Venus and Mars; semidiameter and parallax for the sun; and semidiameter, augmentation, and parallax for the moon.

819. Artificial-horizon corrections.—When an artificial horizon is used, index correction (and any others of the first group of article 816) is first applied. The result is then divided by two. Other corrections are then applied to the result, as applicable, in the same manner as for observations using the visible horizon. The sun and full moon are normally observed by bringing the lower limb of one image tangent to the upper limb of the other image. The lower limb is observed if the image seen in the horizon mirror is *above* the image seen in the artificial horizon, unless an inverting telescope is used, when the opposite relationship holds. With a gibbous or crescent moon, judgment may be needed to establish the positions of the limbs. In some cases better results may be obtained by superimposing one image over the other, as with a planet or star. When this is done, the *center* of the body has been observed, and no correction is applied for semidiameter (or irradiation, phase, or augmentation). There is no correction for dip (or sea-air temperature) when an artificial horizon is used.

820. Artificial-horizon sextant corrections are the same as those for observations made by the use of the visible horizon, with two notable exceptions. First, there is no correction for dip (or sea-air temperature difference or wave height), none for semidiameter (or irradiation, phase, or augmentation), and usually none for index correction (or instrument correction). Second, because of the lower accuracy normally obtainable by artificial-horizon sextant, corrections are normally made only to the nearest whole minute of arc. As a result of these differences, refraction is the only correction normally applied, except in the case of the moon, where parallax is also applied.

821. Corrections by *Nautical Almanac*.—In the *Nautical Almanac*, certain corrections or parts of corrections are combined. Index correction, of course, is not included because this depends upon adjustment of the sextant. The various correction tables are as follows:

"*Sun*," on the inside front cover and facing page, gives mean refraction, mean semidiameter for each of two periods during the year, and mean solar parallax. The table on the inside front cover, and repeated on the loose bookmark, is of the critical type, with altitude as the entering value. Thus, a tabulated correction applies to any value of altitude between that given half a line above it and that half a line below it. If an exact tabulated altitude is used to enter the table, the correction half a line *above* it should be used. In ordinary navigation, index correction, dip, and the correction from this table are needed for correcting marine sextant observations of the sun. For low altitudes or extremes of temperature or atmospheric pressure, a correction from the table on almanac page A4 (or tables 23 and 24 of this volume) should be applied.

"*Stars and planets*," on the inside front cover and repeated on the loose bookmark, gives mean refraction only, for the main tabulation. This is a critical type table, with altitude as the entering argument. The correction is always negative. In ordinary navigation, index correction, dip, and the correction from this table are the only ones needed for stars and the planets Jupiter and Saturn. For Venus and Mars, an additional correction for parallax and phase is given to the right of the main tabulation. The entering altitudes are limited to those occuring during twilight. If observations are made at other times, this additional correction should not be applied even though the altitude may fall within the tabulated range.

"*Dip*," on the inside front cover and repeated on the loose bookmark, is for dip of the horizon. An abbreviated dip table is also given on the page facing the inside back cover. The tables are of the critical type, and the entering argument is the height of the observer's eye, in feet and meters, above the surface of the sea. The correction, always negative, applies to all observations made with the visible sea horizon as a reference.

"*Additional Correction Tables*" for *nonstandard conditions*, given on almanac page A4, provides an additional correction for nonstandard temperature and atmospheric pressure. The sign of each correction is indicated. Equivalent information is given, with increased range of entering values, in tables 23 and 24 of this volume.

"*Altitude Correction Tables—Moon*," on the inside back cover and facing page, gives mean refraction, semidiameter, augmentation, and parallax. The entering argument is altitude for the upper portion of the table, and altitude and horizontal parallax for the lower portion. The combined correction is always positive, but 30′ is to be subtracted from the altitude of the upper limb. In ordinary navigation, index correction, dip, and the correction from this table are needed in correcting marine sextant observations of the moon.

The various separate corrections available from the *Nautical Almanac* can be found as follows:

Dip. Dip table on inside front cover and repeated on loose bookmark, and on the page facing the inside back cover.

Refraction. Mean refraction from "Stars and Planets" table on inside front cover and repeated on loose bookmark, and on the facing page.

Semidiameter. For the sun, the semidiameter for the middle day of each page opening of this daily page section is given at the bottom of the sun GHA column. For the moon, semidiameter for each day is given at the bottom of the moon data columns. The values given are for GMT 1200 on the dates indicated.

Parallax. For the sun, parallax in altitude can be considered 0′.1 for altitudes 0° to 70°07′, and 0′.0 for higher altitudes, with negligible error. This is based upon the mean value of 8″.80. For the moon, horizontal parallax each hour is tabulated on the daily pages. Parallax in altitude is this value multiplied by the cosine of the altitude.

If artificial-horizon sextant altitudes of the sun or moon are corrected by *Nautical Almanac*, the upper and lower limb corrections can be found and the average computed.

822. Corrections by *Air Almanac*.—In the *Air Almanac*, various corrections as applicable to hand-held marine sextant observations are given separately in critical type tables, to the nearest whole minute (nearest two or five minutes of refraction for low altitudes), as follows:

Dip. Inside back cover.

Refraction. Near the back. Aboard ship use the values for zero height.

Air temperature. Near the back. This is shown, not as a separate correction, but as an adjustment to mean refraction. Instructions for use of the table are given within the table.

Semidiameter. For the sun and moon, on the A.M. and P.M. pages, below the moon's P in A. Values given are for GMT 1200.

Parallax. For the moon, in the P in A table on the A.M. and P.M. pages. Horizontal parallax is the value for 0° altitude.

823. Correcting altitudes of the sun.—In the normal practice of navigation, sun observations obtained by marine sextant with the visible horizon as reference are corrected as shown in the following examples:

Example 1.—On June 2, 1975, the lower limb of the sun is observed with a marine sextant having an IC of (−)2′.0, from a height of eye of 38 feet. The hs is 51°28′.4.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Solution.—

(1)

	+ ☉	−
IC		2′.0
D		6′.0
☉	15′.2	
sum	15′.2	8′.0
corr.		(+)7′.2
hs		51°28′.4
Ho		51°35′.6

(2)

	+ ☉	−
IC		2′
D		6′
R		1′
SD	16′	
sum	16′	9′
corr.		(+)7′
hs		51°28′
Ho		51°35′

Example 2.—On June 2, 1975, the upper limb of the sun is observed with a marine sextant having an IC of (+) 1′.0, from a height of eye of 45 feet. The hs is 32°47′.9.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Solution.—

(1)

	+ ☉	−
IC	1′.0	
D		6′.5
☉		17′.3
sum	1′.0	23′.8
corr.		(−)22′.8
hs		32°47′.9
Ho		32°25′.1

(2)

	+ ☉	−
IC	1′	
D		7′
R		2′
SD		16′
sum	1′	25′
corr.		(−)24′
hs		32°48′
Ho		32°24′

A convenient work form is helpful in the solution. Once the form is prepared, the corrections can be entered in any order desired. The symbols ☾ and ☉ are used for the corrections from the sun table on the inside front cover of the *Nautical Almanac*. If additional corrections are used, they are included in the same manner as those shown. Observations by artificial horizon and by artificial-horizon sextant, and low-altitude observations and back sights, are discussed elsewhere in this chapter.

824. Correcting altitudes of the moon.—Moon observations by marine sextant with the visible horizon as reference are normally corrected as shown in the following examples:

Example 1.—At about GMT 1100 on June 2, 1975, the lower limb of the moon is observed with a marine sextant having an IC of (+) 3′.2, from a height of eye of 32 feet. The hs is 18°04′.6.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Solution.—

(1)

	+	☾	−
IC	3′.2		
D			5′.5
☾	62′.5		
L	0′.8		
sum	66′.5		5′.5
corr.	(+)1°01′.0		
hs	18°04′.6		
Ho	19°05′.6		

(2)

	+	☾	−
IC	3′		
D			6′
R			3′
SD	15′		
P	51′		
sum	69′		9′
corr.		(+) 60′	
hs		18°05′	
Ho		19°05′	

Example 2.—At about GMT 0900 on June 2, 1975, the upper limb of the moon is observed with a marine sextant having an IC of (−)1′.6, from a height of eye of 70 feet. The hs is 66°47′.3.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Solution.—

(1)

	+	☾	−
IC			1′.6
D			8′.1
☾	33′.1		
U	3′.2

The typical work forms shown are useful in problems of this type. The symbol ☾ is used for the correction from the upper part of the moon correction table on the inside back cover, and facing page, of the *Nautical Almanac*. The symbols L and U are used for the corrections from the lower part of this table. Observations by artificial horizon, and by artificial-horizon sextant, and low-altitude observations and back sights, are discussed elsewhere in this chapter, as are additional corrections for use when unusual accuracy is desired.

825. Correcting altitudes of planets.—When Venus and Mars are observed by marine sextant using the visible horizon as reference, sextant altitudes are normally corrected as shown in the following example:

Example.—On June 19, 1975, Venus is observed with a marine sextant having no IC, from a height of eye of 28 feet. The hs is 44°21′.3.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Solution.—

(1)

	+	V	−
IC	−		−
D			5′.1
☆-P			1′.0
add'l	0′.3		
sum	0′.3		6′.1

hs			44°21′.3
Ho			44°15′.5

(2)

	+	V	−
IC	−		−
D			5′
R			1′
sum	−		6′
corr.			(−)6′
hs			44°21′
Ho			44°15′

For Jupiter and Saturn, no additional correction is given. Correction of observations of these bodies is the same as corrections of star observations (art. 826). Work forms are useful. The symbol ☆-P is used for the correction taken from the "Star-Planet" table on the inside front cover of the *Nautical Almanac*. If additional corrections are to be used, for results of unusual accuracy or low altitudes, they are included in the form in the same manner as those shown. Observations by artificial horizon and by artificial-horizon sextant, and low-altitude observations and back sights are discussed elsewhere in this chapter.

826. Correcting altitudes of stars.—Star observations by marine sextant, using the visible horizon as reference, are normally corrected as shown in the following example:

Example.—Miaplacidus is observed with a marine sextant having an IC of (+)1′.0, from a height of eye of 50 feet. The hs is 27°54′.0.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Solution.—

(1)

	+	☆	−
IC	1′.0		
D			6′.9
☆-P			1′.8
sum	1′.0		8′.7
corr.			(−)7′.7

Ho			27°46′

Work forms for such problems are helpful. Additional corrections, used when unusual accuracy is desired, are included in the same manner as those shown. Observations by artificial horizon and by artificial-horizon sextant, and low-altitude observations and back sights, are discussed elsewhere in this chapter.

827. Low altitudes are normally avoided because of large and variable refraction. But sometimes these are the only observations available. This is particularly true in polar regions, where the sun may be the only celestial body available, and may not

reach an altitude of more than a few degrees over a considerable period. In lower latitudes the sun may appear briefly just before sunset or just after sunrise. Low-altitude observations can supply useful information if additional corrections are applied. Reliable lines of position can generally be obtained from low-altitude observations, but when conditions are abnormal, the errors introduced are generally larger than for higher altitudes, and the precautions of article 806 should be particularly observed.

In correcting low-altitude observations, which for normal conditions can be defined as those less than 5°, first apply corrections from the first two groups of article 816 to obtain apparent altitude (ha). Normally, this includes only index correction and dip. Then apply the remaining corrections, using apparent altitude when an altitude is needed for entering correction tables. The corrections normally applied are mean refraction, air temperature, atmospheric pressure, semidiameter (as applicable), and parallax (for the sun and moon).

In practice, sextant altitudes are corrected in the usual manner, except that additional corrections are applied, and the process is divided into two parts. The use of apparent altitude for finding parallax introduces an error but this is too small (less than 0′.1) for practical consideration. If the *Nautical Almanac* is used, corrections for altitudes between the horizon and 10° are given in a noncritical type table on almanac page A3. The correction for a negative altitude can be obtained by extrapolation without introducing a significant error for values obtained at ship heights of eye. A combined temperature-atmospheric pressure correction can be obtained from the table on almanac page A4. This table is intended for use without interpolation between columns. Separate corrections can be obtained from tables 23 and 24 of this volume, which provide interpolated values for greater accuracy. They also provide greater range of temperature and atmospheric pressure.

To correct a low altitude of the sun, then, apply index correction and dip to sextant altitude to find apparent altitude. Using this altitude as an entering value, find the following corrections and apply them to apparent altitude:

sun correction (☉ or ☉), from page A3 of the *Nautical Almanac;*

combined temperature-atmospheric pressure correction (TB), from page A4 of the *Nautical Almanac* (separate corrections for temperature (T) and atmospheric pressure (B) from tables 23 and 24, respectively, can be used *in place of* the combined correction).

If the *Air Almanac* is used, the mean refraction and air temperature corrections can be combined by using the factor in the refraction table. A semidiameter correction of 16′ is added if the lower limb is observed, and subtracted if the upper limb is observed. Since corrections are to whole minutes only, parallax is not used for the sun. In summary, apply index correction and dip to sextant altitude to find apparent altitude. Using this altitude as an entering value, where needed, apply the following corrections to apparent altitude:

refraction (adjusted for air temperature) (R), from table near back of *Air Almanac;*

atmospheric pressure (B), from table 24;

semidiameter (SD), 16′ (add if lower limb, and subtract if upper limb).

Example 1.—On June 2, 1975, the lower limb of the sun is observed with a marine sextant having an IC of (+)1′.8 from a height of eye of 45 feet. The hs is 1°24′.4, air temperature 88°F, and atmospheric pressure 29.78 inches.

Required.—Ho using (1) *Nautical Almanac,* (2) tables 23 and 24, and (3) *Air Almanac.*

The larger intervals given in the *Air Almanac* refraction table may introduce additional error. In this example, the temperature is changed to Celsius (centigrade), giving a value of 31°. The factor at a height of 0 feet corresponding to this temperature is 0.9. With this and the apparent altitude, the combined refraction and air temperature correction is found to be as shown. Approximately the same result would have been obtained by correcting for mean refraction (without the factor) and temperature (from table 23) separately.

If the moment at which either limb is tangent to the horizon is noted, an observation of 0° altitude has been made without a sextant.

Example 2.—On June 2, 1975, the sun is observed at sunset as the upper limb drops below the horizon, from a height of eye of 38 feet. The air temperature is (−)10° F, and atmospheric pressure 30.06 inches. Double extrapolation would be needed to solve this problem by the *Nautical Almanac*. A better solution is provided by means of tables 23 and 24.

Required.—Ho using (1) tables 23 and 24, and (2) *Air Almanac*.

Corrections are applied algebraically. Therefore, for negative altitudes a negative correction is *numerically* added, and a positive correction is *numerically* subtracted.

To correct low altitudes of the moon, apply index correction and dip to sextant altitude to find apparent altitude. Using this altitude as an entering value, find the following corrections and apply them to apparent altitudes:

moon correction (☾), from inside back cover, and facing page, of *Nautical Almanac;*

lower or upper limb correction (L or U), from inside back cover, and facing page, of *Nautical Almanac;*

additional correction (add'l, (−)30′, for upper limb observation only);

combined temperature-atmospheric pressure correction (TB), from page A4 of the *Nautical Almanac* (separate corrections for temperature (T) and atmospheric pressure (B) from tables 23 and 24, respectively, can be used in place of the combined correction).

If the *Air Almanac* is used, correct the apparent altitude by applying the following corrections:

refraction (adjusted for air temperature) (R), from table near back of *Air Almanac;*

atmospheric pressure (B), from table 24;

semidiameter, from daily page;

parallax, from daily page.

Example 3.—At GMT $17^h14^m27^s$ on June 2, 1975, the upper limb of the moon is observed with a marine sextant having no IC, from a height of eye of 33 feet. The hs is 2°35′.4, air temperature 63° F, and atmospheric pressure 29.81 inches.

Required.—Ho using (1) *Nautical Almanac*, (2) tables 23 and 24, and (3) *Air Almanac.*

Solution.—

A lower limb solution would be the same, except that an L correction would have been used from the *Nautical Almanac* and there would be no "add'l" correction, and in the *Air Almanac* solution the sign of the semidiameter correction would be reversed. The moon correction table on the inside back cover, and facing page, of the *Nautical Almanac* extends to a minimum altitude of 0°. The corrections for negative altitudes can be found by extrapolation.

To correct low altitudes of the planets Venus and Mars, apply index correction and dip to sextant altitude to find apparent altitude. Using this altitude as an entering value, find the following corrections and apply them to apparent altitude:

star-planet correction (☆-P), from page A3 of the *Nautical Almanac;*
additional correction (add'l), from page A2 of the *Nautical Almanac;*
combined temperature-atmospheric pressure correction (TB), from page A4 of the *Nautical Almanac* (separate corrections for temperature (T) and atmospheric pressure (B) from tables 23 and 24, respectively, can be used *in place of* the combined correction).

If the *Air Almanac* is used, correct the apparent altitude by applying the following corrections:

refraction (adjusted for air temperature) (R), from table near back of *Air Almanac;*
atmospheric pressure (B), from table 24.

Example 4.—On November 28, 1975, Mars is observed with a marine sextant having an IC of (+)3′.5, from a height of eye of 17 feet. The hs is 4°02′.6, air temperature 2° F, and atmospheric pressure 29.67 inches.

Required.—Ho using (1) *Nautical Almanac*, (2) tables 23 and 24, and (3) *Air Almanac.*

The solution for Jupiter and Saturn, and for stars, is identical with that of example 4, except that the additional correction (phase and parallax) is omitted.

828. Back sights.—An altitude measured by facing *away* from the celestial body being observed is called a **back sight**. It may be used when an obstruction, such as another vessel, obscures the horizon under the body; when that horizon is indistinct; or when observations are made in both directions, either to determine dip or to avoid error due to suspected abnormal dip. Such an observation is possible only when the arc of the sextant is sufficiently long to permit measurement of the angle, which is the supplement of the altitude. For such an observation of the sun or moon, the lower limb is observed when the image is brought below the horizon, appearing as a normal upper limb observation, and vice versa. To correct such an altitude, subtract it from 180° and reverse the sign of corrections of the first two groups of article 816 (normally only index correction and dip).

Example.—On June 2, 1975, a back sight is taken of the lower limb of the sun, with a marine sextant having an IC of (−)2′.0, from a height of eye of 24 feet. The measured sextant altitude is 118°41′.4.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac.*

Solution.—

(1)

	+	☉	−

829. Correcting horizontal angles.—When a marine sextant is used to measure the horizontal angle between two objects, the result is not usually desired to a precision that makes correction necessary, unless the sextant has an unusually large index error. However, if precise results are desired, corrections of the first group only of article 816 are applied. If a personal error exists, it is not likely to be the same as for altitudes. For measuring angles between two objects differing widely in altitude, as between two stars, it is not likely that results will be required to such precision that additional correction for the third, fourth, and fifth groups of article 816 will be needed. If they are, the method of application can be determined from the principles of spherical trigonometry (art. 142). In this case, the altitudes of both bodies will also be needed. Corrections for the second group of article 816 are not applicable.

Problems

819a. At about GMT 0800 on June 2, 1975, the following bodies are observed with marine sextants having an IC of (+)2′.2, using an artificial horizon: sun (lower limb) hs 134°33′.9, moon (upper limb) hs 77°23′.4, Venus hs 98°04′.6, Schedar hs 43°24′.4.

Required.—Ho of each observation using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Sun Ho 67°33′.6, moon Ho 39°09′.1, Venus Ho 49°02′.6, Schedar Ho 21°40′.9; (2) sun Ho 67°34′, moon Ho 39°09′, Venus Ho 49°03′, Schedar Ho 21°41′.

819b. At about GMT 0300 on June 2, 1975, the following bodies are observed with bubble sextants having no IC: sun hs 23°51′, moon hs 52°20′, Jupiter hs 63°18′, Eltanin hs 24°45′.

Required.—Ho of each observation using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) and (2) Sun Ho 23°49′, moon Ho 52°52′, Jupiter Ho 63°18′, Eltanin Ho 24°43′.

823a. On June 2, 1975, the lower limb of the sun is observed with a marine sextant having an IC of (+)1′.8, from a height of eye of 34 feet. The hs is 41°34′.8.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Ho 41°45′.8; (2) Ho 41°46′.

823b. On June 2, 1975, the upper limb of the sun is observed with a marine sextant having no IC, from a height of eye of 30 feet. The hs is 15°21′.7.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Ho 14°57′.1; (2) Ho 14°57′.

823c. On June 2, 1975, the lower limb of the sun is observed with a marine sextant having an IC of (−)1′.3, from a height of eye of 43 feet. Another ship is between the observer and the horizon, at a distance of 1.4 miles from the observer. The water line of this ship is used as the horizontal reference. The hs is 25°18′.2.

Required.—Ho using table 22 and (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Ho 25°12′.9; (2) Ho 25°13′.

824a. At about GMT 2100 on June 2, 1975, the lower limb of the moon is observed with a marine sextant having an IC of (−)2′.5, from a height of eye of 55 feet. The hs is 47°35′.5.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Ho 48°16′.3; (2) Ho 48°16′.

824b. At about GMT 2300 on June 2, 1975, the upper limb of the moon is observed with a marine sextant having an IC of (+)4′.0, from a height of eye of 12 feet. The hs is 22°58′.3.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Ho 23°31′.8; (2) Ho 23°32′.

825a. On June 18, 1975, Mars is observed with a marine sextant having an IC of (+)2′.2, from a height of eye of 60 feet. The hs is 34°11′.7.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Ho 34°05′.1; (2) Ho 34°05′.

825b. Jupiter is observed with a marine sextant having an IC of (−)1′.0, from a height of eye of 27 feet. The hs is 11°23′.9.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Ho 11°13′.2; (2) Ho 11°13′.

826. Alpheratz is observed with a marine sextant having no IC, from a height of eye of 42 feet. The hs is 38°20′.3.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Ho 38°12′.8; (2) Ho 38°13′.

827a. On June 2, 1975, the lower limb of the sun is observed with a marine sextant having an IC of (−) 2′.3, from a height of eye of 24 feet. The hs is 2°04′.6, air temperature 65° F, and atmospheric pressure 30.81 inches.

Required.—Ho using (1) *Nautical Almanac*, (2) tables 23 and 24, and (3) *Air Almanac*.

Answers.—(1) Ho 1°55′.1; (2) Ho 1°55′.1; (3) Ho 1°55′.

827b. On July 2, 1975, the sun is observed as the upper limb drops below the horizon at sunset, from a height of eye of 19 feet. The air temperature is 16° F, and atmospheric pressure 29.90 inches.

Required.—Ho using (1) *Nautical Almanac*, (2) tables 23 and 24, and (3) *Air Almanac*.

Answers.—(1) Ho (−)0°59′.9 (2) Ho (−)0°57′.8; (3) Ho (−)0°58′.

827c. At GMT $6^h03^m29^s$ on June 2, 1975, the upper limb of the moon is observed with a marine sextant having an IC of (+)2′.6, from a height of eye of 35 feet. The hs is 1°12′.6, air temperature (−)23° F, and atmospheric pressure 29.04 inches.

Required.—Ho using (1) tables 23 and 24, and (2) *Air Almanac*.

Answers.—(1) Ho 1°22′.3; (2) Ho 1°20′.

827d. At GMT $12^h44^m01^s$ on June 2, 1975, the lower limb of the moon is observed with a marine sextant having an IC of (+)3′.2, from a height of eye of 22 feet. The hs is 0°24′.4, air temperature 40° F, and atmospheric pressure 29.94 inches.

Required.—Ho using (1) *Nautical Almanac*, (2) tables 23 and 24, and (3) *Air Almanac*.

Answers.—(1) Ho 1°01′.2; (2) Ho 1°01′.5; (3) Ho 0°58′.

827e. On January 19, 1975, Venus is observed with a marine sextant having an IC of (−)0′.5, from a height of eye of 31 feet. The hs is 3°29′.8, air temperature 55° F, and atmospheric pressure 30.15 inches.

Required.—Ho using (1) *Nautical Almanac*, (2) tables 23 and 24, and (3) *Air Almanac*.

Answers.—(1) Ho 3°10′.7; (2) Ho 3°10′.7; (3) Ho 3°10′.

827f. Saturn is observed with a marine sextant having an IC of (−)2′.3, from a height of eye of 37 feet. The hs is 4°39′.2, air temperature 76° F, and atmospheric pressure 28.89 inches.

Required.—Ho using (1) *Nautical Almanac*, (2) tables 23 and 24, and (3) *Air Almanac*.

Answers.—(1) Ho 4°21′.1; (2) Ho 4°21′.1; (3) Ho 4°21′.

827g. Gienah is observed with a marine sextant having no IC, from a height of eye of 44 feet. The hs is 2°46′.1, air temperature 35° F, and atmospheric pressure 29.92 inches.

Required.—Ho using (1) *Nautical Almanac*, (2) tables 23 and 24, and (3) *Air Almanac*.

Answers.—(1) Ho 2°23′.4; (2) Ho 2°36′.6; (3) Ho 2°21′.

828. On June 2, 1975, a back sight is taken of the lower limb of the sun, with a marine sextant having an IC of (+)1′.7, from a height of eye of 49 feet. The measured sextant altitude is 141°04′.9.

Required.—Ho using (1) *Nautical Almanac*, and (2) *Air Almanac*.

Answers.—(1) Ho 39°15′.0; (2) Ho 39°15′.

829. The horizontal angle between two objects is measured with a marine sextant having an IC of (+)4′.0. The measured angle is 85°14′.6.

Required.—Corrected angle.

Answer.—Corrected angle 85°18′.6.

CHAPTER IX

SIGHT REDUCTION

901. Introduction.—The process of deriving from a celestial observation the information needed for establishing a line of position is called **sight reduction.** The observation itself consists of measuring the altitude of a celestial body and noting the time. The process of finding such a line of position may be divided into six steps:

1. Correction of sextant altitude (ch. VIII).
2. Determination of GHA and declination (ch. VII).
3. Selection of assumed position and finding local hour angle or meridian angle at that point.
4. Computation of altitude and azimuth (ch. VII).
5. Comparison of computed and observed altitudes.
6. Plot of the line of position.

Broadly speaking, tables which assist in any of these steps can be considered **sight reduction tables.** However, the expression is generally limited to tables intended primarily for computation of altitude and azimuth. A great variety of such tables exists. In volume I various methods of sight reduction, including graphical and mechanical solutions, are contrasted. All are based, directly or indirectly, upon solution of the navigational triangle (art. 508). Thus, the process of sight reduction, in its limited sense, is one of converting coordinates of the celestial equator system (art. 504) to those of the horizon system (art. 506).

The correction of the sextant altitude (hs) to find observed altitude (Ho) is not necessarily performed first. If any form of time other than GMT is used for timing the observation, it is first converted to GMT because this is the kind of time used for entering the almanacs. From the almanac, the GHA and declination are determined.

902. Selection of the assumed position (AP).—The following variables are needed to compute the altitude and azimuth:

1. Latitude (L).
2. Declination (d).
3. Local hour angle (LHA) or meridian angle (t).

Except for declination, these variables are dependent upon the position from which the altitude and azimuth are to be computed for the time of the observation. Although the dead reckoning or estimated position can be used, unnecessary interpolation can can be avoided when using modern sight reduction tables by selecting an AP for the reduction that will result in two of the three variables being exact entry values or table arguments. In these tables altitudes and azimuth angles are given for each whole degree of latitude and each whole degree of either meridian angle or local hour angle. Since the assumed position should be within 30′ of the actual position, the whole degree of latitude *nearest* to the DR or EP at the time of the sight is selected as the **assumed latitude** (*a*L). The **assumed longitude** (*a*λ) is also selected within 30′ of the DR or EP so that no minutes of arc will remain after it is applied to GHA. This means that

in west longitude the minutes of $a\lambda$ must be the same as those of GHA; while in east longitude the minutes of $a\lambda$ must be equal to 60′ minus the minutes of GHA.

903. Finding the local hour angle and meridian angle.—Meridian angle is the angular distance that the celestial body is east or west of the celestial meridian. It is found from local hour angle (LHA), which, in turn, is found from Greenwich hour angle by adding east longitude or subtracting west longitude. A time diagram (art. 504) is useful in visualizing this relationship.

Example 1.—The GHA is 168°42′.6.

Required.—The LHA and t at (1) long. 137°24′.6W, and (2) 158°24′.7E.

Solution.—

(1)	GHA	168°42′.6	(2)	GHA	168°42′.6
	λ	137°24′.6W		λ	158°24′.7E
	LHA	31°18′.0		LHA	327°07′.3
	t	31°18′.0W		t	32°52′.7E

In west longitude, if GHA is less than longitude, add 360° to GHA before subtracting. In east longitude, if the sum exceeds 360°, subtract this amount. If LHA is less than 180°, it is numerically equal to meridian angle, which is labeled W (west). If LHA is greater than 180°, t is 360°−LHA and is labeled E (east).

Example 2.—The GHA is 168°42′.6; observations are made at (1) long. 137°24′.6W, and (2) long. 158°24′.7E.

Required.—The $a\lambda$ providing whole degrees of LHA and t.

Solution.—

(1)	GHA	168°42′.6	(2)	GHA	168°42′.6
	$a\lambda$	137°42′.6W		$a\lambda$	158°17′.4E
	LHA	31°00′.0		LHA	327°00′.0
	t	31°00′.0W		t	33°00′.0E

904. Comparison of computed and observed altitudes.—After appropriate corrections are applied to the **sextant altitude** (**hs**), the **observed altitude** (**Ho**) is obtained. For the instant of observation, the altitude and azimuth at some convenient **assumed position** (**AP**) near the actual position of the observer are determined by calculation or equivalent process. The difference between this **computed altitude** (**Hc**) and Ho is the **altitude intercept** (*a*), sometimes called **altitude difference.**

Since *a* is the difference in altitude at the assumed and actual positions, it is also the difference in zenith distance, and therefore the difference in radii of the circles of equal altitude at the two places. The position having the greater altitude is on the circle of smaller radius, and hence is closer to the GP of the body. In figure 904 the AP is shown on the inner circle. Hence, Hc is greater than Ho.

The altitude intercept, the numerical difference between Hc and Ho, is customarily expressed in nautical miles (minutes of arc), and labeled **T** or **A** to indicate whether the line of position is **toward** or **away** from the GP, as measured from the AP.

Two useful aids in labeling the intercept are: **C**oast **G**uard **A**cademy for **C**omputed **G**reater **A**way, and **Ho Mo To** for **Ho Mo**re **To**ward.

For example,

Hc	37°51′.6	Hc	61°57′.3
Ho	37°43′.9	Ho	62°12′.7
a	7′.7A	*a*	15′.4T

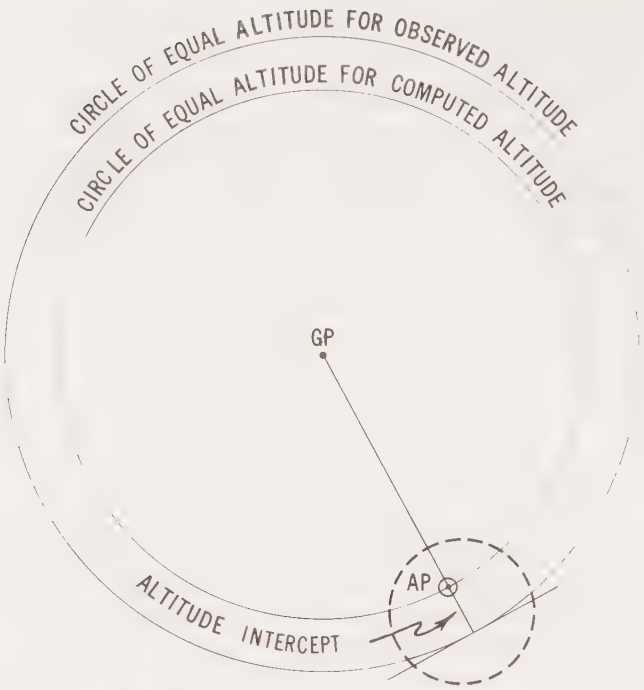

FIGURE 904.—The basis for the line of position from a celestial observation.

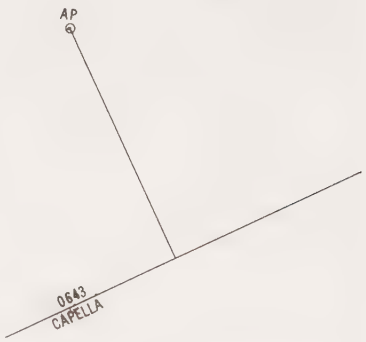

FIGURE 905.—A line of position from observation of the star Capella at 0643.

905. Plot of the line of position.—The line of position can be plotted using part of the information within the broken circle of figure 904, as shown in figure 905. First, the AP is plotted. The circle of equal altitude through this position is not needed, and is not plotted. From the AP the azimuth line is measured toward or away from the GP as appropriate, and the altitude intercept is measured along this line. At the point thus located, a line is drawn perpendicular to the azimuth line. This perpendicular is the line of position.

906. Complete solution.—The complete solution includes all of the parts listed in article 901. Because of the various alternatives available for the separate parts, a large number of variations might be used in the complete solution. The following example combines some of the most commonly used variations.

Example.—On June 1, 1975, the GMT 0825 dead reckoning position of a ship is lat. 35°34′.4N, long. 66°20′.2W. Kochab is observed at an altitude of 34°54′.6 from a height of eye of 40 feet using a sextant having an index error of (+)2′.0.

Required.—The a and Zn from the GMT 0825 DR.

Solution.—By cosine-haversine formula and tables 33 and 34.

Sight Reduction by Cosine-Haversine Formula (art. 712 and 713)

Caution.—When the quantity K is between 82° and 98°, it is good practice to either discard the sight or to interpolate log secant (B) of R from the log cosecant (A) of R.

CHAPTER X

THE SAILINGS

1001. The sailings.—In the solution of problems involved in the sailings, the following quantities are used:

1. *Latitude* (L). The latitude of the point of departure is designated L_1; that of the point of arrival or the destination, L_2; middle (mid) or mean latitude, Lm; latitude of the vertex of a great circle, L_v; and latitude of any point on a great circle, L_x.

2. *Mean latitude* (Lm). Half the arithmetical sum of the latitudes of two places on the same side of the equator.

3. *Middle or mid latitude* (Lm). The latitude at which the arc length of the parallel separating the meridians passing through two specific points is exactly equal to the departure in proceeding from one point to the other. The mean latitude is normally used for want of a practicable means of determining the middle latitude.

4. *Difference of latitude* (*l* or D. Lat.).

5. *Meridional parts* (M). The meridional parts of the point of departure are designated M_1, and of the point of arrival or the destination, M_2.

6. *Meridional difference* (m).

7. *Longitude* (λ). The longitude of the point of departure is designated λ_1; that of the point of arrival or the destination, λ_2; of the vertex of a great circle, λ_v; and of any point on a great circle, λ_x.

8. *Difference of longitude* (DLo).

9. *Departure* (p or Dep.).

10. *Course* or *course angle* (Cn or C).

11. *Distance* (D or Dist.).

The various kinds of sailings are:

1. **Plane sailing** is a method of solving the various problems involving a single course and distance, difference of latitude, and departure, in which the earth, or that part traversed, is regarded as a plane surface. Hence, the method provides solution for latitude of the point of arrival, but not for longitude of this point, one of the spherical sailings being needed for this problem. Because of the basic assumption that the earth is flat, this method should not be used for distances of more than a few hundred miles.

2. **Traverse sailing** combines the plane sailing solutions when there are two or more courses. This sailing is a method of determining the equivalent course and distance made good by a vessel steaming along a series of rhumb lines.

3. **Parallel sailing** is the interconversion of departure and difference of longitude when a vessel is proceeding due east or due west. This was a common occurrence when the sailings were first employed several hundred years ago, but only an incidental situation now.

4. **Middle-** (or **mid-**) **latitude sailing** involves the use of the mid or mean latitude for converting departure to difference of longitude when the course is not due east or due west and it is assumed such course is steered at the mid latitude.

5. **Mercator sailing** provides a mathematical solution of the plot as made on a Mercator chart. It is similar to plane sailing, but uses meridional difference and difference of longitude in place of difference of latitude and departure, respectively.

6. **Great-circle sailing** involves the solution of courses, distances, and points along a great circle between two points, the earth being regarded as a sphere.

7. **Composite sailing** is a modification of great-circle sailing to limit the maximum latitude.

1002. Traverse tables, such as table 3, can be used in the solution of any of the sailings except great-circle and composite. Table 3 is basically the tabulation of the solutions of plane right triangles. Because the solutions are for integral values of the course angle and the distance, interpolation for intermediate values may be required. Through appropriate interchanges of the headings of the columns, solutions for other than plane sailing can be effected. For the solution of the plane right triangle, any number N in the distance (Dist.) column is the hypotenuse; the number opposite in the difference of latitude (D. Lat.) column is N times the cosine of the acute angle; and the other number opposite in the departure (Dep.) column is N times the sine of the acute angle. Or, the number in the D. Lat. column is the value of the side adjacent, and the number in the Dep. column is the value of the side opposite the acute angle. Hence, if the acute angle is the course angle, the side adjacent in the D. Lat. column is meridional difference m; the side opposite in the Dep. column is DLo. If the acute angle is the midlatitude of the formula p=DLo cos Lm, then DLo is any value N in the Dist. column, and the departure is the value N×cos Lm in the D. Lat. column.

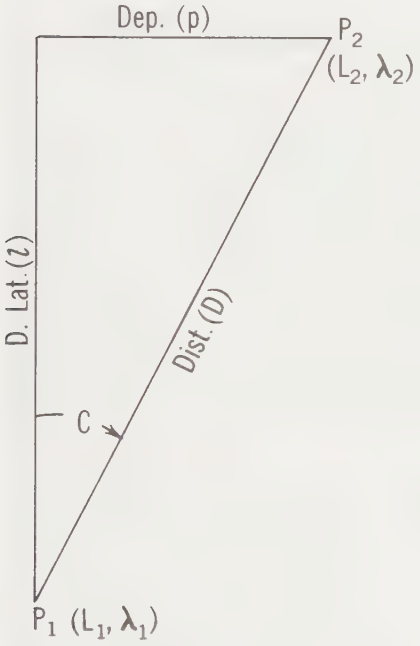

FIGURE 1003.—The plane sailing triangle.

1003. Plane sailing.—In plane sailing the figure formed by the meridian through the point of departure, the parallel through the point of arrival, and the course line is considered a plane right triangle. This is illustrated in figure 1003, in which P_1 and P_2 are the points of departure and arrival, respectively. The course angle and the three sides are as labeled. From this triangle:

$$\cos C=\frac{l}{D} \qquad \sin C=\frac{p}{D} \qquad \tan C=\frac{p}{l}.$$

From the first two of these formulas the following relationships can be derived:

$$l=D \cos C \qquad D=l \sec C \qquad p=D \sin C.$$

The usual problems solved by plane sailing are: (1) given the course and distance, find the difference of latitude and the departure; and (2) the reverse of this. It is good practice to label *l*, N or S, and p, E or W, to aid in identification of the quadrant of the course. Logarithmic and traverse table solutions are illustrated in the following examples:

Example 1.—A vessel steams 188.0 miles on course 005°.

Required.—(1) Difference of latitude, (2) departure.

Solution.—By computation:

D 188.0 mi.	log 2.27416	log 2.27416
C 005°	l cos 9.99834	l sin 8.94030
(1) l 187.3 N	log 2.27250	
(2) p 16.4 mi. E		log 1.21446

In the solution by computation, 2.27416 is the logarithm ("log") of 188.0, and 9.99834 is the logarithmic cosine ("l cos") of 5°.

The labels (N, S, E, W) of l, p, and C are determined by noting the direction of motion or the relative positions of the two places.

Solution.—By inspection of table 3:

Refer to figure 1003a. Enter table 3 and turn the pages to find course 005° at the top of the page. Using the column headings at the top of the table, opposite 188 in the Dist. column extract D. Lat. 187.3 and Dep. 16.4.

(1) D. Lat. 187.3N.

(2) Dep. 16.4 mi. E.

If the course were 085°, 095°, 265°, or 275°, the column headings at the bottom of the table would be used.

FIGURE 1003a.—Extract from table 3.

If, in example 1, the vessel steamed 18.8 miles instead of 188 miles, the values for D. Lat. and Dep. would be extracted opposite 188 in the Dist. column and then be divided by 10.

Example 2.—A ship has steamed 136.0 miles north and 203.0 miles west.

Required.—(1) Course, (2) distance.

Solution.—By computation: (1) $\tan C = \frac{p}{l}$ (2) $D = l \sec C$

p	203.0 mi.W	log	2.30750	
l	136.0N	log (−)	2.13354	log 2.13354
C	N56°10.8W	l tan	0.17396	l sec 0.25447
(2) D	244.3 mi.			log 2.38801
(1) Cn	303°.8			

Solution.—By inspection of table 3:

Refer to figure 1003b. Enter table 3 and turn the pages until the numbers 136 and 203 are found abreast each other in the columns labeled D. Lat. and Dep., respectively. This occurs most nearly on the page for course angle 56°. Therefore, the course is 304°. Interpolating for intermediate values, the corresponding number in the Dist. column is about 244.3.

(1) C 304°.

(2) D 244.3 mi.

FIGURE 1003b.—Extract from table 3.

When the course is near 090° or 270°, the solution of C to the nearest 0°.1 only may introduce a large error in distance.

1004. Traverse sailing.—A **traverse** is a series of courses, or a track consisting of a number of course lines, as might result from a sailing vessel beating into the wind. **Traverse sailing** is the finding of a single equivalent course and distance.

Solution is usually made by means of the traverse tables, the distance to the north or south and that to the east or west on each course being tabulated, the algebraic sum of difference of latitude and departure being found, and the result being converted to course and distance.

Example.—A ship steams as follows: course 158°, distance 15.5 miles; course 135°, distance 33.7 miles; course 259°, distance 16.1 miles; course 293°, distance 39.0 miles; course 169°, distance 40.4 miles.

Required.—Equivalent single (1) course, (2) distance.

Solution.—Solve for each leg as in example 1, article 1003. Tabulate the answers as follows:

Course	Dist.	N	S	E	W
°	*mi.*	*mi.*	*mi.*	*mi.*	*mi.*
158	15.5		14.4	5.8	
135	33.7		23.8	23.8	
259	16.1		3.1		15.8
293	39.0	15.2			35.9
169	40.4		39.7	7.7	
		15.2	81.0	37.3	51.7
			15.2		37.3
(1)	(2)				
192.3	67.3		65.8		14.4

For course 158°, the values for D. Lat. and Dep. are extracted opposite 155 in the Dist. column. The values are then divided by 10 and rounded off to the nearest tenth.

Convert *l* 65′.8 S, p 14.4 mi. W to equivalent single course and distance.

1005. Parallel sailing consists of the interconversion of departure and difference of longitude. It is the simplest form of spherical sailing. The formulas for these transformations are:

$$DLo = p \sec L \qquad p = DLo \cos L.$$

Example 1.—The DR latitude of a ship on course 090° is 49°30′N. The ship steams on this course until the longitude changes 3°30′.

Required.—The departure.

Solution.—By computation: p=DLo cos L

DLo 210′E	log 2.32222
L 49°30′N	*l* cos 9.81254
p 136.4 mi. E	log 2.13476

Solution.—By inspection of table 3:

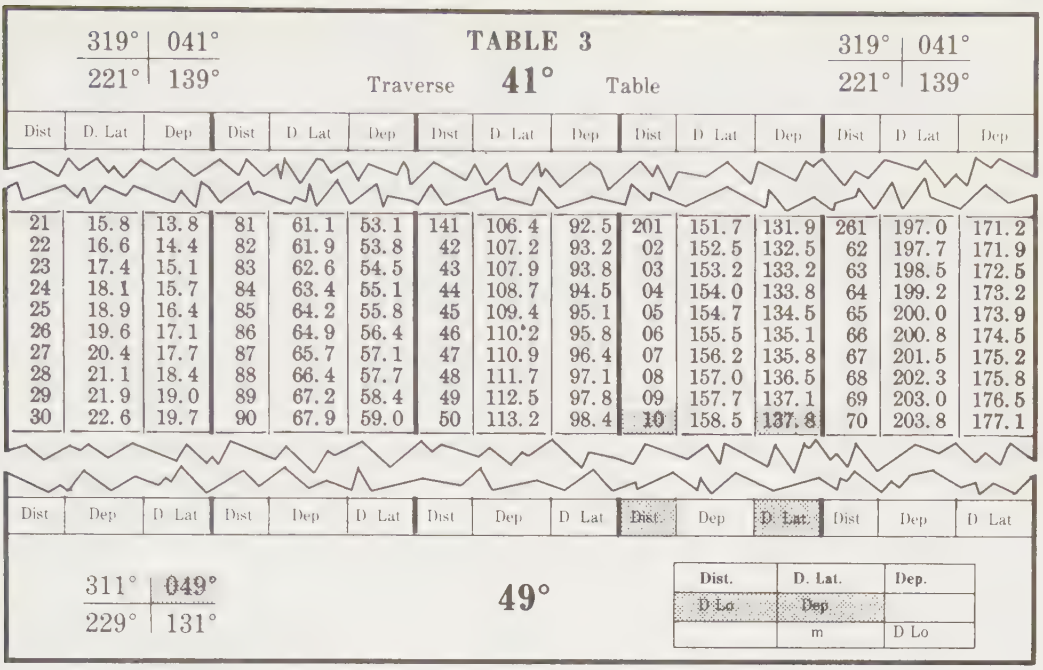

Refer to figure 1005a. Enter table 3 with latitude as course angle and substitute DLo as the heading of the Dist. column and Dep. as the heading of the D. Lat. column. As the table is computed for integral degrees of course angle (or latitude), the tabulations in the pages for 49° and 50° must be interpolated for the intermediate value (49°30′). The departure for latitude 49° and DLo 210′ is 137.8 miles. The departure for latitude 50° and DLo 210′ is 135.0 miles. Interpolating for the intermediate latitude, the departure is 136.4 miles.

Example 2.—The DR latitude of a ship on course 270° is 38°15′S. The ship steams on this course for a distance of 215.5 miles.

Required.—The change in longitude.

Solution.—By computation: DLo=p sec L

p	215.5 mi. W	log 2.33345
L	38°15′S	*l* sec 0.10496
DLo	274′.4W	log 2.43841
DLo	4°34′.4W	

319° | 041°
221° | 139°

FIGURE 1005a.—Extracts from table 3.

Dep. 136.4 mi E.

Solution.—By inspection of table 3:

Refer to figure 1005b. Enter table 3 with latitude as course angle and substitute DLo as the heading of the Dist. column and Dep. as the heading of the D. Lat. column. As the table is computed for integral degrees of course angle (or latitude), the tabulations in the pages for 38° and 39° must be interpolated for the minutes of latitude. Corresponding to Dep. 215.5 miles in the former is DLo 273′.5, and in the latter DLo 277′.3. Interpolating for the minutes of latitude, the DLo is 274′.4.

DLo 274′.4W or 4°34′.4W.

1006. Middle-latitude sailing, popularly called mid-latitude sailing, combines plane sailing and parallel sailing. Plane sailing is used to find difference of latitude and departure when course and distance are known, or vice versa. Parallel sailing is used to interconvert departure and difference of longitude. The mean latitude (Lm) is normally used for want of a practicable means of determining the middle latitude, the latitude at

which the arc length of the parallel separating the meridians passing through two specific points is exactly equal to the departure in proceeding from one point to the other. The formulas for these transformations are:

$$DLo = p \sec Lm \qquad p = DLo \cos Lm.$$

The mean latitude (Lm) is half the arithmetical sum of the latitudes of two places on the same side of the equator. The mean latitude is labeled N or S to indicate whether it is north or south of the equator. If a course line crosses the equator, that part on each side (the north latitude and south latitude portions, respectively) should be solved separately.

This sailing, like most elements of navigation, contains certain simplifying approximations which produce answers somewhat less accurate than those yielded by more rigorous solutions. For ordinary purposes, however, the results are more accurate than the navigation of the vessel using them. From time to time suggestions have been made that a correction be applied to eliminate the error introduced by assuming that the meridians of the point of departure and of the destination converge uniformly (as the two sides of a plane angle), rather than as the sine of the latitude (approximately). The proposed correction usually takes the form of some quantity to be added to or subtracted from the middle latitude to obtain a "corrected middle latitude" for use in the solution. Tables giving such a correction have been published for both spherical and spheroidal earths. However, the actual correction is not a simple function of the middle latitude and the difference of longitude, as assumed, because the basic formulas of the sailing are themselves based upon a sphere, rather than a spheroid. Hence, the use of such a correction is misleading, and may introduce more error than it eliminates. The use of any correction is not considered justified; if highly accurate results are required, a different method should be used.

Example 1.—A vessel steams 1,253.0 miles on course 070° from lat. 15°17′.0 N, long. 151°37′.0 E.

Required.—(1) Latitude and (2) longitude of the point of arrival.

Solution.—By computation: (1) $l = D \cos C$; $p = D \sin C$ (2) $DLo = p \sec Lm$

D 1253.0 mi.	log 3.09795		log 3.09795
C 070°	l cos 9.53405		l sin 9.97299
l 428′.6 N	log 2.63200		
p 1177.4 mi. E			log 3.07094
Lm 18°51′.3 N			l sec 0.02395
DLo 1244′.2 E			log 3.09489
L_1 15°17′.0 N	L_1 15°17′.0 N		
l 7°08′.6 N	½ l 3°34′.3 N		
(1) L_2 22°25′.6 N	Lm 18°51′.3 N		

λ_1	151°37′.0 E
DLo	20°44′.2 E
(2) λ_2	172°21′.2 E

Solution.—By inspection of table 3:

Refer to figure 1006a. Enter table 3 with course 070° and distance 1,253 miles to find D. Lat. 429′ and Dep. 1,178 miles. Because a number as high as 1,253 is not tabulated in the Dist. column, the values for D. Lat. and Dep. are obtained for a distance of 125.3 miles, and then multiplied by 10. The latitude of the point of arrival being 22°26′N, the mean latitude (Lm) is 18°51′.5N.

p	875.4 mi. W	log	2.94220	
l	498′.0 S	log (−)	2.69723	log 2.69723
C	S 60°21′.9 W	l tan	0.24497	l sec 0.30586
(2) D	1007.1 mi.			log 3.00309
(1) Cn	240°.4			

The labels (N, S, E, W) of l, p, and C are determined by noting the direction of motion or the relative positions of the two places.

Solution.—By inspection of table 3:

Refer to figure 1006b. Enter table 3 with the mean latitude as course angle and substitute DLo as the heading of the Dist. column and Dep. as the heading of the D. Lat. column. Since the table is computed for integral values of course angle (or latitude), it is usually necessary to extract the value of departure for values just less and just greater than the Lm, and then interpolate for the minutes of Lm. In this case where Lm is almost 13°, enter table 3 with Lm 13° and DLo 898′.3 to find Dep. 875 miles. The departure is found for DLo 89′.9, and then multiplied by 10.

Reenter table 3 and turn the pages until the numbers 875 and 498 are found abreast each other in the columns labeled Dep. and D. Lat., respectively. Because these high numbers are not tabulated, it is necessary to divide the departure and difference of latitude by 10, and then inspect to find 87.5 and 49.8 abreast each other. This occurs most nearly on the page for course angle 60° (fig. 1006c). Interpolating for intermediate values, the corresponding number in the Dist. column is about 100.5. Multiplying this number by 10, the distance is found as about 1,005 miles.

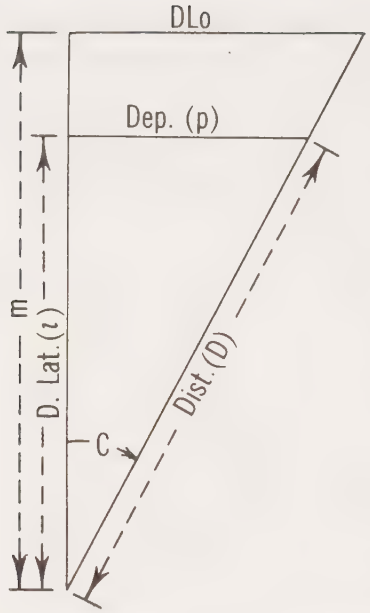

FIGURE 1007a.—Mercator sailing relationships.

The labels (N, S, E, W) of l, p, DLo, and C are determined by noting the direction of motion or the relative positions of the two places.

When the course is near 090° or 270°, the solution of C to the nearest 0°.1 only may introduce a large error in distance.

1007. Mercator sailing problems are solved graphically when measurement is made on a Mercator chart. Graphical solution can also be made as shown in figure 1007a. The lower part is identical with the plane sailing triangle, figure 1003. For mathematical solution the formulas of Mercator sailing are:

$$\tan C=\frac{DLo}{m} \qquad DLo=m \tan C.$$

Following solution of course angle by Mercator sailing, the solution of distance is by means of the plane sailing formula:

$$D=l \sec C.$$

Solution can be made by computation or by traverse table.

Example 1.—A ship at lat. 32°14′.7N, long. 66°28′.9W is to head for a point near Chesapeake Light, lat. 36°58′.7N, long. 75°42′.2W.

Required.—(1) Course, (2) distance.

Solution.—By computation: (1) $\tan C=\frac{DLo}{m}$ (2) $D=l \sec C$

L_1 32°14′.7 N	M_1 2033.3	λ_1 66°28′.9 W	
L_2 36°58′.7 N	M_2 2377.0	λ_2 75°42′.2 W	
l 4°44′.0 N	m 343.7	DLo 9°13′.3 W	
l 284′.0 N		DLo 553′.3 W	
DLo 553′.3 W	log 2.74296		
m 343.7	log (−) 2.53618		
C N58°09′.1W	l tan 0.20678	l sec 0.27764	
l 284′.0 N		log 2.45332	
(2) D 538.2 mi.		log 2.73096	
(1) Cn 301°.8			

Solution.—By inspection of table 3:

Refer to figure 1007b. Substitute m as the heading of the D. Lat. column and DLo as the heading of the Dep. column. Turn the pages of table 3 until the numbers 343.7 and 553.3 are found abreast in the columns relabeled m and DLo, respectively.

Because a number as high as 343.7 is not tabulated in the m column, it is necessary to divide m and DLo by 10. Then inspect to find 34.4 and 55.3 abreast in the m and DLo columns, respectively. This occurs most nearly on the page for course angle 58° or course 302°.

Reenter table 3 with course 302° to find Dist. for D. Lat. 284′.0.

C N58°W.
(1) Cn 302°.

FIGURE 1007b.—Extract from table 3 composed of parts of left- and right-hand pages for course angle 58°.

Example 2.—A ship at lat. 75°31′.7N, long. 79°08′.7W, in Baffin Bay, steams 263.5 miles on course 155°.

Required.—(1) Latitude and (2) longitude of point of arrival.

Solution.—By computation:

D 263.5 mi.	log 2.42078	
C 155°	l cos 9.95728	l tan 9.66867
l 238′.8 S	log 2.37806	
m 846.3		log 2.92752
DLo 394′.6 E		log 2.59619
L_1 75°31′.7 N	M_1 7072.4	λ_1 79°08′.7 W
l 3°58′.8 S		DLo 6°34′.6 E
(1) L_2 71°32′.9 N	M_2 6226.1	(2) λ_2 72°34′.1 W
	m 846.3	

The labels (N, S, E, W) of l, DLo, and C are determined by noting the direction of motion or the relative positions of the two places.

If the course is near 090° or 270°, a small error in C introduces a large error in DLo. The solution for C to the nearest 0°.1 only may introduce a large error in distance if the course is near 090° or 270°.

Solution.—By inspection of table 3:

Refer to figure 1007c. Enter table 3 with course 155° and Dist. 263.5 miles to find D. Lat. 238′.8. The latitude of the point of arrival is found by subtracting the D. Lat. from the latitude of the point of departure. Determine the meridional difference by table 5 (m=846.3).

Reenter table 3 with course 155° to find the DLo corresponding to m=846.3.

Substitute meridional difference m as the heading of the D. Lat. column and DLo as the heading of the Dep. column. Because a number as high as 846.3 is not tabulated in the m column, it is necessary to divide m by 10 and then inspect the m column for a value of 84.6. Interpolating as necessary, the latter value is opposite DLo 39′.4. The DLo is 394′ (39′.4×10). The longitude of the point of arrival is found by applying the DLo to the longitude of the point of departure.

1008. Rhumb lines and great circles.—The principal advantage of a **rhumb line** is that it maintains constant true direction. A ship following the rhumb line between two places does not change true course. A rhumb line makes the same angle with all meridians it crosses and appears as a straight line on a Mercator chart. It is adequate for most purposes of navigation, bearing lines (except long ones, as those obtained by radio) and course lines both being plotted on a Mercator chart as rhumb lines, except in high latitudes. The equator and the meridians are great circles, but may be considered special cases of the rhumb line. For any other case, the difference between the rhumb line and the great circle connecting two points increases (1) as the latitude increases, (2) as the difference of latitude between the two points decreases, and (3) as the difference of longitude increases. It becomes very great for two places widely separated on the same parallel of latitude far from the equator.

A great circle is the intersection of the surface of a sphere and a plane through the center of the sphere. It is the largest circle that can be drawn on the surface of the sphere, and is the shortest distance, along the surface, between any two points on the sphere. Any two points are connected by only one great circle unless the points are antipodal (180° apart on the earth), and then an infinite number of great circles passes through them. Thus, two points on the same meridian are not joined by any great circle other than the meridian, unless the two points are antipodal. If they are the

poles, *all* meridians pass through them. Every great circle bisects every other great circle. Thus, except for the equator, every great circle lies half in the northern hemisphere and half in the southern hemisphere. Any two points 180° apart on a great circle have the same latitude numerically, but contrary names, and are 180° apart in longitude. The point of greatest latitude is called the **vertex**. For each great circle there is one of these in each hemisphere, 180° apart. At these points the great circle is tangent to a parallel of latitude, and hence its direction is due east-west. On each side of these vertices the direction changes progressively until the intersection with the equator is reached, 90° away, where the great circle crosses the equator at an angle equal to the latitude of the vertex. As the great circle crosses the equator, its change in direction reverses, again approaching east-west, which it reaches at the next vertex.

On a Mercator chart a great circle appears as a sine curve extending equal distances each side of the equator. The rhumb line connecting any two points of the great circle on the same side of the equator is a chord of the curve, being a straight line nearer the equator than the great circle. Along any intersecting meridian the great circle crosses at a higher latitude than the rhumb line. If the two points are on opposite sides of the equator, the direction of curvature of the great circle relative to the rhumb line changes at the equator. The rhumb line and great circle may intersect each other, and if the points are equal distances on each side of the equator, the intersection takes place at the equator.

1009. Great-circle sailing is used when it is desired to take advantage of the shorter distance along the great circle between two points, rather than to follow the longer rhumb line. The arc of the great circle between the points is called the **great-circle track.** If it could be followed exactly, the destination would be dead ahead throughout the voyage (assuming course and heading were the same). The rhumb line *appears* the more direct route on a Mercator chart because of chart distortion. The great circle crosses meridians at higher latitudes, where the distance between them is less.

The decision as to whether or not to use great-circle sailing depends upon the conditions. The saving in distance should be worth the additional effort, and of course the great circle should not cross land, or carry the vessel into dangerous waters or excessively high latitudes. A slight departure from the great circle or a modification called composite sailing (art. 1011) may effect a considerable saving over the rhumb line track without leading the vessel into danger. If a fix indicates the vessel is a considerable distance to one side of the great circle, the more desirable practice often is to determine a new great-circle track, rather than to return to the original one.

Since a great circle is continuously changing direction as one proceeds along it, no attempt is customarily made to follow it exactly. Rather, a number of points are selected along the great circle, and rhumb lines are followed from point to point, taking advantage of the fact that for short distances a great circle and a rhumb line almost coincide.

1010. Great-circle sailing by computation.—In figure 1010a, 1 is the point of departure, 2 the destination, P the pole nearer 1, $1XV2$ the great circle through 1 and 2, V the vertex, and X any point on the great circle. The arcs $P1$, PX, PV, and $P2$ are the colatitudes of points 1, X, V, and 2, respectively. If 1 and 2 are on opposite sides of the equator, $P2$ is 90° + L_2. The length of arc 1–2 is the great-circle distance between 1 and 2. Arcs 1–2, $P1$, and $P2$ form a spherical triangle. The angle at 1 is the initial great-circle course from 1 to 2, that at 2 the supplement of the final great-circle course (or the initial course from 2 to 1), and that at P the DLo between 1 and 2.

Great-circle sailing by computation usually involves solution for the initial great-circle course; the distance; latitude and longitude, and sometimes the distance, of the

vertex; and the latitude and longitude of various points (X) on the great circle. The computation for initial course and the distance involves solution of an oblique spherical triangle, and any method of solving such a triangle can be used. If 2 is the **geographical position** (**GP**) of a celestial body (the point at which the body is in the zenith), this triangle is solved in celestial navigation, except that 90°—D (the altitude) is desired instead of D. The solution for the vertex and any point X usually involves the solution of right spherical triangles.

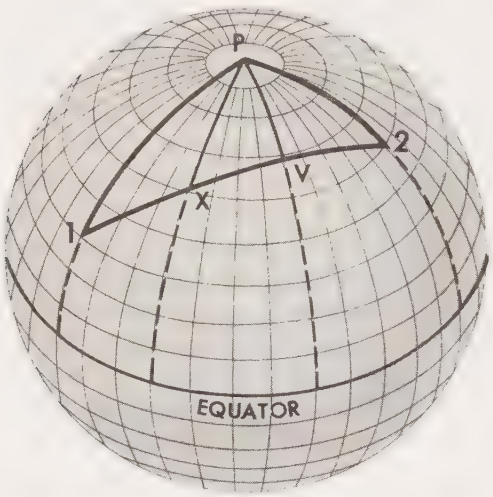

FIGURE 1010a.—The navigational triangle of great-circle sailing.

Although various formulas can be used, haversine formulas are considered most suitable for determining initial course and the distance, as these avoid the ambiguity that may arise through the use of trigonometric functions which do not indicate the quadrant in which the answer lies. In the formulas given below, the subscripts refer to the points indicated in figure 1010a. All terms without subscripts are from 1 to 2, D_v and DLo_v are from 1 to V, and D_{vx} and DLo_{vx} are from V to X. Other quantities can be computed by interchanging 1 and 2 in figure 1010a and using the same formulas. The following formulas are suitable for great-circle sailing by computation:

$$\text{hav } D = \text{hav } DLo \cos L_1 \cos L_2 + \text{hav } l \tag{21}$$

which may be written $\text{hav } D = \text{hav } \theta + \text{hav } l$ (where $\text{hav } \theta = \text{hav } DLo \cos L_1 \cos L_2$) (22)

$$\text{hav } C = \sec L_1 \csc D \,[\text{hav co}L_2 - \text{hav } (D \sim \text{co}L_1)] \tag{23}$$

$$\sin C = \sin DLo \cos L_2 \csc D \tag{24}$$

$$\cos L_v = \cos L_1 \sin C \tag{25}$$

$$\sec L_v = \sec L_1 \csc C \tag{26}$$

$$\sin DLo_v = \cos C \csc L_v \tag{27}$$

$$\csc DLo_v = \sec C \div \csc L_v \tag{28}$$

$$\sin D_v = \cos L_1 \sin DLo_v \tag{29}$$

$$\csc D_v = \sec L_1 \csc DLo_v \tag{30}$$

$$\tan L_x = \cos DLo_{vx} \tan L_v \tag{31}$$

$$\csc L_x = \csc L_v \sec D_{vx} \tag{32}$$

$$\csc DLo_{vx} = \csc D_{vx} \div \sec L_x \tag{33}$$

$$\sec C_x = \csc L_v \csc DLo_{vx} \tag{34}$$

$$\cos DLo_{vx} = \tan L_x \cot L_v. \tag{35}$$

Equation 21 is derived from equation 8b through the substitution of great-circle distance for zenith distance (D for z), latitude of destination for declination (L_2 for d), difference of latitude (l) (for (L∼d), and difference of longitude for meridian angle (DLo for t).

Equation 23 is derived from the cosecant formula, equation 9b:

$$\text{hav } B=[\text{hav } b \text{ hav } (a\sim c)] \csc a \csc c. \tag{9b}$$

Substituting the parts of the navigational triangle of great-circle sailing in equation 9b, angle B is the initial great-circle course angle; side b is the colatitude of the destination, coL_2; side a is the great-circle distance, D; and side c is the colatitude of the point of departure, coL_1.

$$\text{hav } C=[\text{hav } coL_2-\text{hav } (D\sim coL_1)] \csc D \csc (90°-L_1)$$
$$\text{hav } C=\sec L_1 \csc D [\text{hav } coL_2-\text{hav } (D\sim coL_1)]. \tag{23}$$

Equation 24 is derived from the law of sines:

The angles and sides opposite of the oblique spherical triangle shown in figure 1010b have by the law of sines the following relationship:

$$\frac{\sin a}{\sin A}=\frac{\sin b}{\sin B}=\frac{\sin c}{\sin C}. \tag{3d}$$

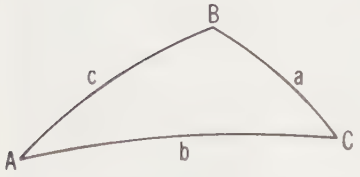

FIGURE 1010b.—Oblique spherical triangle.

FIGURE 1010c.—Navigational triangle of great-circle sailing.

As applied to the navigational triangle of great-circle sailing shown in figure 1010c, the law of sines is stated as:

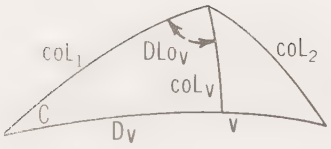

$$\frac{\sin (90°-L_2)}{\sin C}=\frac{\sin D}{\sin DLo}$$
$$\sin C=\sin DLo \cos L_2 \csc D. \tag{24}$$

Equations 25 through 35 are derived by means of Napier's Rules of Circular Parts. In applying the rules to the divided navigational triangle of great-circle sailing shown in figure 1010d, the five sectors of the circular parts diagrams are first completed. Applying the rule that the sine of a middle part equals the product of the cosines of the opposite parts:

$$\sin (90°-L_v)=\cos L_1 \cos (90°-C)$$
$$\therefore \cos L_v=\cos L_1 \sin C \tag{25}$$
$$\sec L_v=\sec L_1 \csc C \tag{26}$$

$$\sin (90°-C)=\cos (90°-DLo_v) \cos (90°-L_v)$$
$$\cos C=\sin DLo_v \sin L_v$$
$$\sin DLo_v=\cos C \csc L_v \tag{27}$$
$$\csc DLo_v=\sec C \div \csc L_v \tag{28}$$

$$\sin D_v=\cos L_1 \cos (90°-DLo_v)$$
$$\sin D_v=\cos L_1 \sin DLo_v \tag{29}$$
$$\csc D_v=\sec L_1 \csc DLo_v. \tag{30}$$

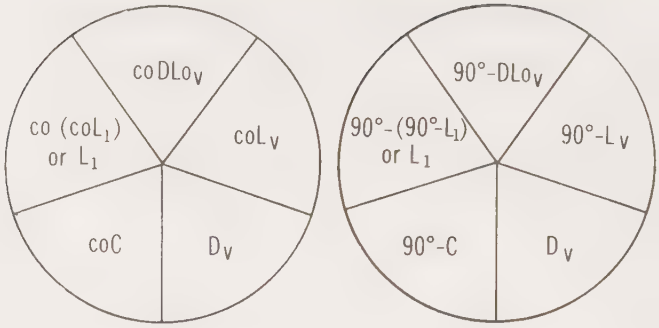

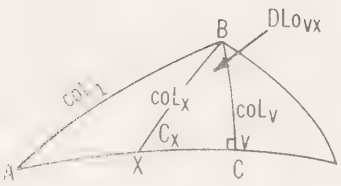

FIGURE 1010d.—Divided navigational triangle and circular parts diagrams.

In applying the rules to the divided navigational triangle shown in figure 1010e, the five sectors of the circular parts diagrams are first completed. Applying the rules that the sine of the middle part equals the product of (1) the tangents of the adjacent parts or (2) the cosines of the opposite parts:

$$\begin{aligned} \sin (90°-\mathrm{DLo}_{vx}) &= \tan \mathrm{L}_x \cot \mathrm{L}_v \\ \cos \mathrm{DLo}_{vx} &= \tan \mathrm{L}_x \cot \mathrm{L}_v \\ \tan \mathrm{L}_x &= \cos \mathrm{DLo}_{vx} \tan \mathrm{L}_v \end{aligned} \tag{31}$$

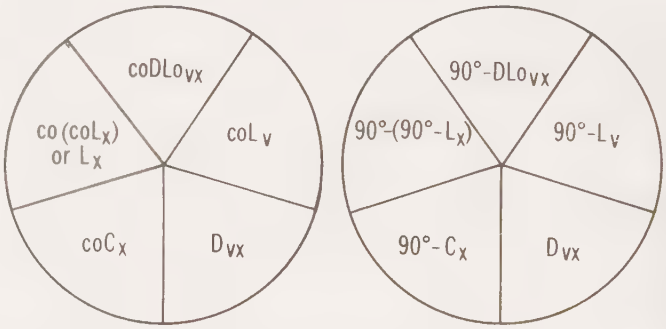

FIGURE 1010e.—Divided navigational triangle and circular parts diagrams.

$$\begin{aligned} \sin \mathrm{L}_x &= \cos (90°-\mathrm{L}_v) \cos \mathrm{D}_{vx} \\ \sin \mathrm{L}_x &= \sin \mathrm{L}_v \cos \mathrm{D}_{vx} \\ \csc \mathrm{L}_x &= \csc \mathrm{L}_v \sec \mathrm{D}_{vx} \end{aligned} \tag{32}$$

$$\begin{aligned} \sin \mathrm{D}_{vx} &= \cos \mathrm{L}_x \cos (90°-\mathrm{DLo}_{vx}) \\ \sin \mathrm{D}_{vx} &= \cos \mathrm{L}_x \sin \mathrm{DLo}_{vx} \\ \csc \mathrm{DLo}_{vx} &= \csc \mathrm{D}_{vx} \div \sec \mathrm{L}_x \end{aligned} \tag{33}$$

$$\begin{aligned} \sin (90°-\mathrm{C}) &= \cos (90°-\mathrm{L}_v) \cos (90°-\mathrm{DLo}_{vx}) \\ \cos \mathrm{C}_x &= \sin \mathrm{L}_v \sin \mathrm{DLo}_{vx} \\ \sec \mathrm{C}_x &= \csc \mathrm{L}_v \csc \mathrm{DLo}_{vx} \end{aligned} \tag{34}$$

$$\begin{aligned} \sin (90°-\mathrm{DLo}_{vx}) &= \tan \mathrm{L}_x \tan (90°-\mathrm{L}_v) \\ \cos \mathrm{DLo}_{vx} &= \tan \mathrm{L}_x \cot \mathrm{L}_v. \end{aligned} \tag{35}$$

Equations 32 and 33 are useful for finding points at approximately equal distances, along the great-circle, from the vertex. If D_{vx} is greater than 90° (5400 nautical miles), L_x is of contrary name to L_v, and DLo_{vx} is greater than 90°.

Equation 24 offers a simpler solution than the haversine formula, but unless L_2 is of the same name and equal to or greater than L_1, it leaves doubt as to whether C is less or greater than 90°.

Equation 34 offers an even simpler solution but has the same limitations as equation 24. Further, it requires a knowledge of the position of the vertex.

Equation 35 is useful in determining the longitude (or DLo_{vx}) at which the great-circle crosses selected parallels of latitude. If L_x is of contrary name to L_v, DLo_{vx} is greater than 90°. The formula is also used in composite sailing.

Example.—A ship is proceeding from Manila to Los Angeles. The captain wishes to use great-circle sailing from lat. 12°45′.2N, long. 124°20′.1E, off the entrance to San Bernardino Strait, to lat. 33°48′.8N, long. 120°07′.1W, five miles south of Santa Rosa Island.

Required.—(1) The great-circle distance.

(2) The great-circle course.

(3) The latitude and longitude of the vertex.

(4) The distance from the point of departure to the vertex.

(5) The latitude and longitude of points at DLo intervals of 12° each side of the vertex.

Solution.—By equations 22 and 23.

(1) Determine difference of longitude (DLo) and difference of latitude (l). To determine DLo in this case, add the east and west longitudes and subtract from 360°; the DLo is east because the destination is eastward.

(2) Determine the great-circle distance by equation 22, and then use this distance to compute the initial great-circle course by equation 23:

$$\text{hav } D = \text{hav } DLo \cos L_1 \cos L_2 + \text{hav } l$$

which may be written

$$\text{hav } D = \text{hav } \theta + \text{hav } l \text{ (where hav } \theta = \text{hav } DLo \cos L_1 \cos L_2) \qquad (22)$$

$$\text{hav } C = \sec L_1 \csc D \,[\text{hav co}L_2 - \text{hav } (D \sim \text{co}L_1)]. \qquad (23)$$

Distance

(3) To obtain l hav θ of equation 22, add l hav DLo as extracted from table 34 to l cos L_1 and l cos L_2 as extracted from table 33.

(4) From table 34 extract the value of the natural haversine (n hav) of θ corresponding to the l hav θ (the value of θ need not be found).

(5) Add the natural haversines of θ and l (as extracted from table 34) to obtain the natural haversine corresponding to the distance.

(6) From table 34 extract the distance in arc units corresponding to the n hav value of 0.61331.

λ_1	124°20′.1 E		
λ_2	120°07′.1 W	*Add*	
DLo	115°32′.8 E	l hav 9.85468	
L_1	12°45′.2 N	l cos 9.98915	
L_2	33°48′.8 N	l cos 9.91953	*Add*
θ		l hav 9.76336	n hav 0.57991
l	21°03′.6 N		n hav 0.03340
(1) D	103°05′.9		n hav 0.61331

Course

(7) Determine the values of coL_2 and $(D\sim coL_1)$ to be used in calculating the initial great-circle course angle by equation 23. CoL_2 is $(90°-L_2)$ if L_1 and L_2 are of the same name, and $(90°+L_2)$ if of contrary name. $D\sim coL_1$ is always the numerical difference between D and coL_1.

(8) From table 33 extract values of l sec L_1 and l csc D. These logarithms are to be added to the logarithm of the difference of the natural haversines of coL_2 and $(D\sim coL_1)$.

(9) From table 34 extract the values of the natural haversines of coL_2 and $(D\sim coL_1)$; subtract n hav $(D\sim coL_1)$ from n hav coL_2.

(10) From table 34 extract the value of the log haversine corresponding to n hav of coL_2 minus $(D\sim coL_1)$.

(11) Add l sec L_1, l csc D, and l[hav coL_2−hav$(D\sim coL_1)$].

(12) For the l hav value found in (11), extract the corresponding degrees of arc as the initial great-circle course angle.

				Add
L_1	12°45′.2N			l sec 0.01085
D	103°05′.9	*Subtract*		l csc 0.01145
coL_2	56°11′.2	n hav 0.22175		
$D\sim coL_1$	25°51′.1	n hav (−)0.05004		
		n hav 0.17171		l hav 9.23480
(2) Cn	050°.3		C N50°19′.3E	l hav 9.25710

The course and distance solutions are shown in a more compact format below.

λ_1	124°20′.1E			
λ_2	120°07′.1W			
DLo	115°32′.8E	l hav 9.85468		
L_1	12°45′.2N	l cos 9.98915		l sec 0.01085

$D\sim coL_1$	25°51′.1	n hav (−)0.05004		
		n hav 0.17171		l hav 9.23480
(2) Cn	050′.3		C N50°19′.3E	l hav 9.25710
(1) D	6185.9 mi.			

The Vertex

(13) The latitude of the vertex, L_v, is always numerically equal to or greater than L_1 or L_2. If C is less than 90°, the nearer vertex is toward L_2; but if C is greater than 90°, the nearer vertex is in the opposite direction. The vertex nearer L_1 has the same name as L_1.

(14) Using equation 25 to determine L_v, add the l sin C to the l cos L_1 to obtain l cos L_v.

$$\cos L_v = \cos L_1 \sin C \qquad (25)$$

L_1	12°45′.2N	l cos 9.98915
C	N50°19′.3E	l sin 9.88629
L_v	41°21′.2N	l cos 9.87544

(15) Using equation 27 to determine the difference of longitude of λ_1 and the vertex (DLo_v), add l cos C to l csc L_v to obtain l sin DLo_v.

$$\sin DLo_v = \cos C \csc L_v \tag{27}$$

C	N50°19′.3E		l cos 9.80514
L_v	41°21′.2N		l csc 0.17999
λ_v	160°34′.4W	DLo_v 75°05′.5E	l sin 9.98513

(16) Using equation 29 to determine the distance to the vertex (D_v), add l cos L_1 to l sin DLo_v to obtain l sin D_v.

$$\sin D_v = \cos L_1 \sin DLo_v \tag{29}$$

L_1	12°45′.2N		l cos 9.98915
λ_v	160°34′.4W	DLo_v 75°05′.5E	l sin 9.98513
D_v	70°28′.5	l sin 9.98513	l sin 9.97428
D_v	4228.5 mi.		

The vertex solution is shown in a more compact form below.

	L_1	12°45′.2N	l cos 9.98915		l cos 9.98915
	C	N50°19′.3E	l sin 9.88629	l cos 9.80514	
(3)	L_v	41°21′.2N	l cos 9.87544	l csc 0.17999	
	λ_v	160°34′.4W	DLo_v 75°05′.5E	l sin 9.98513	l sin 9.98513
	D_v	70°28′.5			l sin 9.97428
(4)	D_v	4228.5 mi.			

Points on the Great-Circle Track

(17) DLo_v and D_v of the nearer vertex are never greater than 90°. However, when L_1 and L_2 are of contrary name, the other vertex, 180° away, may be the better one to use in the solution for points on the great-circle track if it is nearer the mid point of the track.

(18) The latitudes of points on the great-circle track can be determined for equal DLo intervals each side of the vertex using equation 31.

(19) Using equation 31, the l cos DLo_{vx} is added to the l tan L_v to obtain l tan L_x:

$$\tan L_x = \cos DLo_{vx} \tan L_v \tag{31}$$

DLo_{vx}	12°00′.0	l cos 9.99040	DLo_{vx}	24°00′.0	l cos 9.96073
L_v	41°21′.2N	l tan 9.94457	L_v	41°21′.2N	l tan 9.94457
L_x	40°43′.6N	l tan 9.93497	L_x	38°48′.1N	l tan 9.90530
λ_v	160°34′.4W		λ_v	160°34′.4W	
λ_x	172°34′.4W	(12° W of λ_v)	λ_x	175°25′.6E	(24° W of λ_v)
λ_x	148°34′.4W	(12° E of λ_v)	λ_x	136°34′.4W	(24° E of λ_v)

(20) L_x has the same name as L_v if DLo_{vx} is less than 90°; if DLo_{vx} is greater than 90°, L_x is of contrary name. The great-circle is a symmetrical curve about the vertex. Hence, any given DLo can be applied to λ_v in both directions (E and W) to find two points having the same latitude. For example, one point on the great circle 12° W of the vertex is at lat. 40°43′.6N, long. 172°34′.4W. A second point 12° E of the vertex is at lat. 40°43′.6N, long. 148°34′.4W.

The solution for points on the great-circle track is shown in a compact form below.

DLo_{vx}	12°00′.0	24°00′.0	36°00′.0	48°00′.0	60°00′.0	72°00′.0
$l \cos DLo_{vx}$	9.99040	9.96073	9.90796	9.82551	9.69897	9.48998
$l \tan L_v$	9.94457	9.94457	9.94457	9.94457	9.94457	9.94457
$l \tan L_x$	9.93497	9.90530	9.85253	9.77008	9.64354	9.43455
(5) L_x	40°43′.6 N	38°48′.1 N	35°27′.2 N	30°29′.8 N	23°45′.2 N	15°12′.9 N
λ_x	172°34′.4 W	175°25′.6 E	163°25′.6 E	151°25′.6 E	139°25′.6 E	127°25′.6 E
λ_x	148°34′.4 W	136°34′.4 W	124°34′.4 W	———	———	———

Alternative Solution for Points on Track

(21) The method of selecting the longitude (or DLo_{vx}) and determining the latitude at which the great-circle crosses the selected meridian provides shorter legs in higher latitudes and longer legs in lower latitudes. Points at desired distances or desired equal intervals of distance on the great circle from the vertex can be determined using equations 32 and 33.

(22) Using equation 32 to determine the latitudes of points at desired great-circle distances from the vertex (300 and 600 miles), l csc L_v is added to l sec D_{vx} (distance from vertex to point on great circle) to obtain l csc L_x:

$$\csc L_x = \csc L_v \sec D_{vx} \tag{32}$$

L_v	41°21′.2N	l csc	10.18000	L_v	41°21′.2N	l csc	10.18000
D_{vx}	5° (300 miles)	l sec	10.00166	D_{vx}	10° (600 miles)	l sec	10.00665
L_x	41°09′.7N	l csc	10.18164	L_x	40°35′.5N	l csc	10.18665

(23) Using equation 33 to determine the longitudes of points at the desired great-circle distances from the vertex, l sec L_x is subtracted from l csc D_{vx} to obtain l csc DLo_{vx}:

$$\csc DLo_{vx} = \csc D_{vx} \div \sec L_x \tag{33}$$

D_{vx}	5° (300 miles)	l csc	11.05970	D_{vx}	10° (600 miles)	l csc	10.76033
L_x	41°09′.7N	l sec (—)	10.12329	L_x	40°35′.5N	l sec (—)	10.11955
DLo_{vx}	6°38′.9	l csc	10.93641	DLo_{vx}	13°13′.1	l csc	10.64078
λ_v	160°34′.4W			λ_v	160°34′.4W		
λ_x	167°13′.3W (west of vertex)			λ_x	173°47′.5W (west of vertex)		
λ_x	153°55′.5W (east of vertex)			λ_x	147°21′.3W (east of vertex)		

1011. Composite sailing.—When the great circle would carry a vessel to a higher latitude than desired, a modification of great-circle sailing, called **composite sailing,** may be used to good advantage. The composite track consists of a great circle from the point of departure and tangent to the limiting parallel, a course line along the parallel, and a great circle tangent to the limiting parallel and through the destination.

Solution of composite sailing problems is most easily made by means of a great-circle chart. Lines from the point of departure and the destination are drawn tangent

to the limiting parallel. The coordinates of various selected points along the composite track are then measured and transferred to a Mercator chart.

Composite sailing problems can also be solved by computation. For this purpose equation 35 is used:

$$\cos DLo_{vx} = \tan L_x \cot L_v. \tag{35}$$

In the computation, the point of departure and the destination are used successively as point *X*.

Example.—A ship leaves Baltimore, bound for Bordeaux (Royan), France. The captain desires to use composite sailing from lat. 36°57′.7N, long. 75°42′.2W, near Chesapeake Light, to lat. 45°39′.1N, long. 1°29′.8W, near the entrance to Grande Passe de l'Ouest, limiting the maximum latitude to 47°N.

Required.—(1) The longitude at which the limiting parallel is reached. (2) The longitude at which the limiting parallel should be left.

Solution.—

L_1 36°57′.7N	*l* tan 9.87651	
L_2 45°39′.1N		*l* tan 0.00988
L_v 47°00′.0N	*l* cot 9.96966	*l* cot 9.96966
DLo_{v1} 45°26′.1E	*l* cos 9.84617	
DLo_{v2} 17°27′.0W		*l* cos 9.97954
(1) λ_{v1} 30°16′.1W		
(2) λ_{v2} 18°56′.8W		

Composite sailing applies only when the vertex lies between the point of departure and the destination.

The remainder of the problem is one of solving the two great circles by great-circle sailing and the east-west portion by parallel sailing. Since both great circles have vertices at the same parallel, computation for C, D, and DLo_{vx} can be made by considering them parts of the *same* great circle with L_1, L_2, and L_v as given and $DLo = DLo_{v1} + DLo_{v2}$. The total distance is the sum of the great-circle and parallel distances. In finding λ_x be careful to apply DLo_{vx} to the correct vertex and in the correct direction.

1012. Great-circle sailing by table 35.—The divided navigational triangle of great-circle sailing is shown in figure 1012a. The parts of the triangle and special constructions are labeled as follows:

L_1, the latitude of the point of departure.
L_2, the latitude of the destination.
λ_1, the longitude of the point of departure.
λ_2, the longitude of the destination.
R, perpendicular let fall from the point of destination upon the meridian of the point of departure. This is an auxiliary part.
X, intersection of R with meridian through point of departure.
K, arc from X to equator. This is an auxiliary part introduced to facilitate solution.

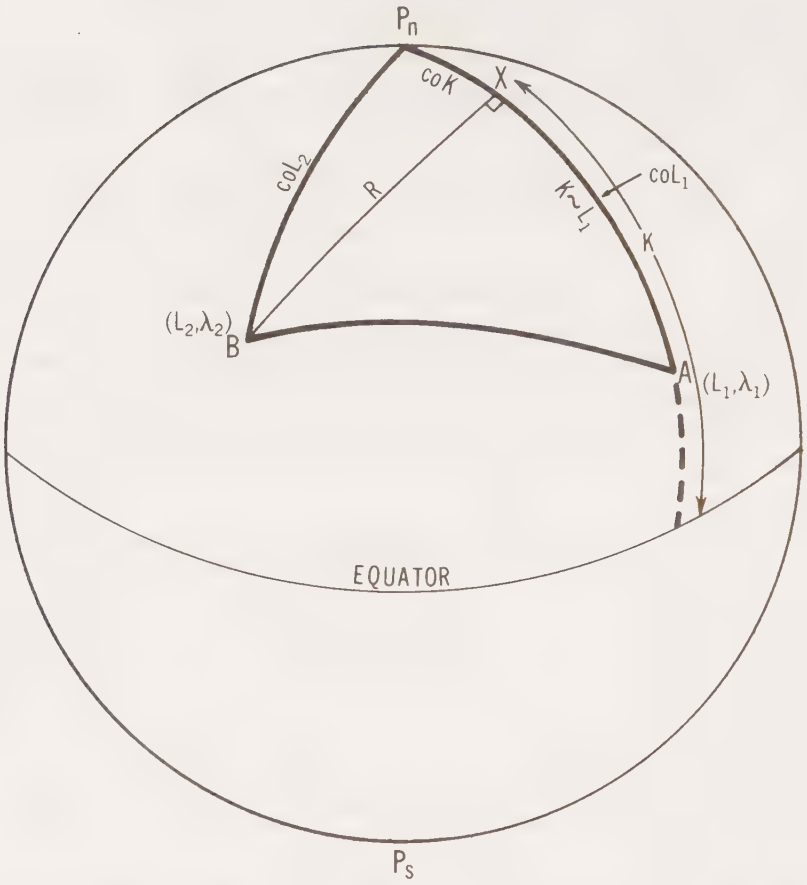

FIGURE 1012a.—The divided navigational triangle of great-circle sailing.

The navigational triangle without auxiliary parts K and R is shown in figure 1012b. In this figure, the parts not identified with figure 1012a are as follows:

C, the initial great-circle course angle.
C_x, the great-circle course angle at point *X* on the great-circle track.
D, great-circle distance.
D_v, distance to vertex from point of departure.
D_{vx}, distance from vertex to point *X* on great-circle track.
DLo_v, difference of longitude between point of departure and vertex.
DLo_{vx}, difference of longitude between the vertex and point *X*.
L_x, the latitude of point *X*.
coL_x, the colatitude of point *X*.
λ_x, the longitude of point *X*.

Formulas

With DLo substituted for t, latitude of destination L_2 substituted for declination, C substituted for Z, and D substituted for z, equations 12a–12d can be stated as:

$$\csc R = \csc DLo \sec L_2 \quad (36)$$
$$\csc K = \csc L_2 \div \sec R \quad (37)$$
$$\sec D = \sec R \sec (K \sim L_1) \quad (38)$$
$$\csc C = \csc R \div \csc D. \quad (39)$$

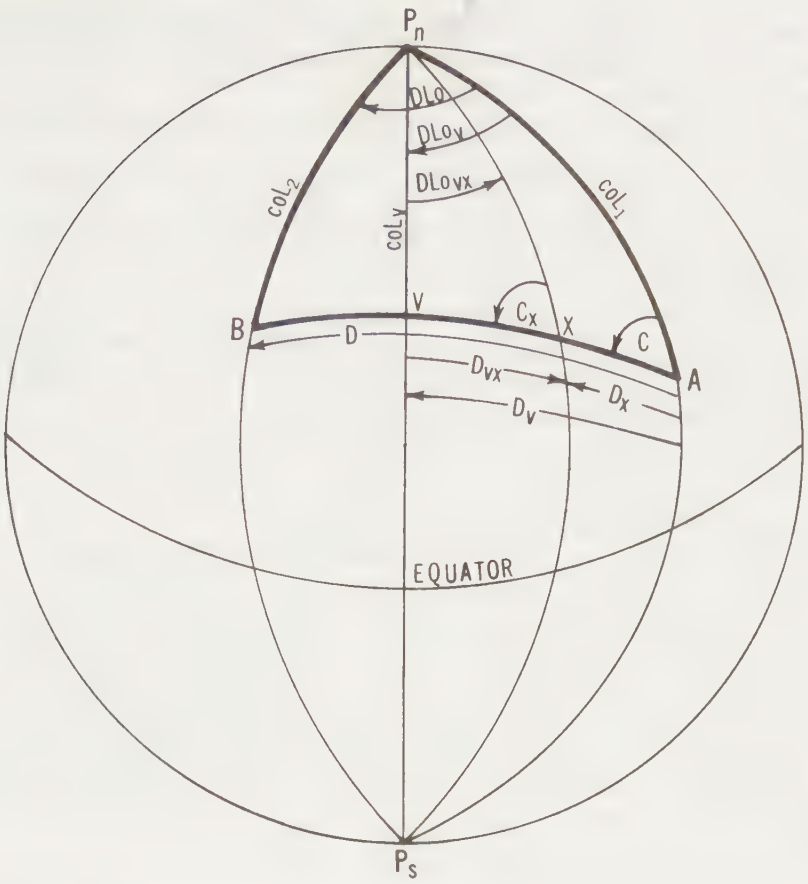

FIGURE 1012b.—The divided navigational triangle of great-circle sailing.

Method of Solution by Table 35

The letters A and B indicate from which column to take their corresponding logarithmic functions multiplied by 100,000.

The following steps are taken to obtain the initial great-circle course angle and the great-circle distance in one combined solution:

1. Enter the table with DLo and take from the A column the nearest tabulated number. Enter the table with L_2 and take the tabulated number from the B column. Add these numbers to obtain the A function of R.

2. Look up the number thus obtained in the A column and take from the B column the opposite tabulated number. Subtract this from the function of L_2 taken from the A column.

3. Enter the A column with the number thus obtained and take out the nearest tabulated value of K, the degrees from the top or bottom of the page and the minutes from the side.

4. Give K the same name as L_2. Combine K with L_1 to obtain ($K \sim L_1$), adding K and L_1 if different names and subtracting the smaller from the larger if same name.

5. Enter the table with ($K \sim L_1$) and take from the B column the nearest tabulated number. Add this to the B function of R.

6. With the number thus obtained, enter the B column and take distance from the table.

7. To compute the initial great-circle course angle, look up the distance in the A column and subtract the number thus obtained from the A function of R which has already been determined.

8. With this number, enter the A column and take out Z (course angle).

Special Rules

Because the great-circle distance D may be greater than 90° (5400 miles), the following special rules must be followed:

Latitude of Departure and Destination are Same Name

(1) When DLo is greater than 90°, take K from the bottom of the table.

(2) Take C from the top of the table when K is greater than L_1. Take C from the bottom of the table when K is less than L_1.

(3) Take distance D from the top of table except when DLo and ($K \sim L_1$) are *both* greater than 90°.

Latitude of Departure and Destination are Contrary Name

(4) When DLo is less than 90°, take K from the top of the table. When DLo is greater than 90°, take K from the bottom of the table.

(5) Take C from the bottom of the table except when ($K \sim L_1$) is greater than 180°.

(6) Take D from the bottom of the table except when DLo and ($K \sim L_1$) are both less than 90°.

(7) When ($K \sim L_1$) exceeds 180°, subtract 180° before entering the table.

Example.—A ship is proceeding from San Francisco to Sydney. The navigator desires to use great-circle sailing from lat. 37°47′.5N, long. 122°27′.8W to lat. 33°51′.7S, long. 151°12′.7E.

Required.—

(1) The great-circle distance.
(2) The initial great-circle course.
(3) The latitude and longitude of the vertex.
(4) The distance of the vertex.
(5) The latitude and longitude of points on the track 6° (360 miles) apart.

Solution.—(1) Follow the steps given in *Method of Solution by Table 35* to obtain the great-circle distance and initial great-circle course angle in one combined solution using the following equations:

$$\csc R = \csc DLo \sec L_2 \quad (36)$$
$$\csc K = \csc L_2 \div \sec R \quad (37)$$
$$\sec D = \sec R \sec (K \sim L_1) \quad (38)$$
$$\csc C = \csc R \div \csc D. \quad (39)$$

λ_2	151°12′.7E				
λ_1	122°27′.8W				
	273°40′.5	*Add*	*Subtract*	*Add*	*Subtract*
DLo	86°19′.5W	A 89.4			
L_2	33°51′.7S	B 8070	A 25403		
R		A 8159.4	B 25206	B 25206	A 8159.4
K	84°33′.0S		A 197		
L_1	37°47′.5N				
$K \sim L_1$	122°20′.5			B 27167	
D: arc	107°25′.5			B 52373	A 2040
	6420+25.5			C N119°42′.5W	A 6119.4
(1) D	6445.5 miles			(2) Cn 240°17′.5	

(2) The latitude and longitude of the vertex are computed using equations 26 and 28:

$$\sec L_v = \sec L_1 \csc C \tag{26}$$

$$\csc DLo_v = \sec C \div \csc L_v. \tag{28}$$

The distance to the vertex is computed using equation 30,

$$\csc D_v = \sec L_1 \csc DLo_v. \tag{30}$$

Practical Rules

If C is greater than 90°, L_v is opposite in name from L_1, and DLo_v and D_v are both taken from the bottom of the table.

			Add	*Subtract*	*Add*
L_1	37°47′.5N		B 10224		B 10224
C	N119°42′.5W		A 6119.4	B 30488	
(3) L_v	46°39′.5S		B 16343.4	A 13830	
DLo_v	137°02′.5W			A 16658	A 16658
λ_1	122°27′.8W	(4) D_v	147°25′		A 26882
	259°30′.3W				
(3) λ_v	100°29′.7E				

Since C is greater than 90°, L_x is opposite in name from L_1, and DLo_v and D_v are both taken from the bottom of the table. Note that the vertex does not fall between the point of departure and destination, but is past the destination.

(3) The latitude and longitude of any point X on the great-circle track are computed using equations 32 and 33.

$$\csc L_x = \csc L_v \sec D_{vx} \tag{32}$$

$$\csc DLo_{vx} = \csc D_{vx} \div \sec L_x. \tag{33}$$

The course angle at any point X is computed using equation 34:

$$\sec C_x = \csc L_v \csc DLo_{vx}. \tag{34}$$

Practical Rules

If D_{vx} is greater than 90°, L_x is opposite in name from L_v, and DLo_{vx} and C_x are both taken from the bottom of the table. C_x is measured from the elevated pole of point X.

To solve for points on the great-circle track at 6° intervals from the vertex using equations 32 and 33:

D_v 147°25′.0
D_x 6°00′.0
D_{vx} 141°25′.0

		Add	*Subtract*	*Add*
	L_v S	A 13830		A 13830
	D_{vx} 141°25′.0	B 10696	A 20506	
(5)	L_x 34°39′.0N	A 24526	B 8479	
	DLo_{vx} 130°42′.0E		A 12027	A 12027
	λ_v 259°30′.3W	C_x N123°27′.5W		B 25857
(5)	λ_x 128°48′.3W			

Note that the value L_v is not set down. Its function is taken directly from the vertex solution. Since D_{vx} is greater than 90°, L_x is north and DLo_{vx} and C_x are taken from the bottom of table.

To facilitate computation of the latitudes and longitudes of points along the great-circle track, equations 32 and 33 may be placed in a special column form. Computation of various points for this problem is illustrated below.

D_v		147°25′	147°25′	147°25′	147°25′	147°25′	147°25′
D_z		6°00′	12°00′	18°00′	36°00′	54°00′	60°00′
D_{vz}		141°25′	135°25′	129°25′	111°25′	93°25′	87°25′
$L_v S$	*Add*	A 13830	13830	13830	13830	13830	13830
D_{vz}		B 10696	14738	19726	43753	122478	134609
L_z		A 24526	28568	33556	57583	136308	148439
L_z		34°39′N	31°12′N	27°30′N	15°24′N	2°29′N	1°52′5S
D_{vz}	*Sub.*	A 20506	15370	11207	3107	77. 3	44. 2
L_z		B 8479	6785	5207	1588	40. 8	23. 3
DLo_{vz}		A 12027	8585	6000	1519	36. 5	20. 9
DLo_{vz}		130°42′0E	124°51′0E	119°26′0E	105°04′0E	92°21′0E	88°13′0E
$\lambda_v W$		259°30′3	259°30′3	259°30′3	259°30′3	259°30′3	259°30′3
$\lambda_z W$		128°48′3	134°39′3	140°04′3	154°26′3	167°09′3	171°17′3

Note that between the fifth and sixth points L_z changes from North to South and that DLo_{vz} is taken from the top of the table instead of the bottom. It will be observed that D_{vz} has become less than 90° between the fifth and sixth points.

As has been previously stated, the vertex in this particular problem lies beyond the destination. When the vertex lies between the point of departure and destination, there are two points on the great-circle track which have the same latitude. In such cases one computation obtains two points on the curve, the latitude being the same for both points, but DLo_{vz} is east in one case and west in the other, two different longitudes being thus obtained by applying DLo_{vz} to λ_v.

Problems

1003a. A vessel steams 117.3 miles on course 214°.

Required.—(1) Difference of latitude, (2) departure, by plane sailing.

Answers.—(1) *l* 97′2S, (2) p 65.6 mi. W.

1003b. A steamer is bound for a port 173.3 miles south and 98.6 miles east of the vessel's position.

Required.—(1) Course, (2) distance, by plane sailing.

Answers.—(1) C 150°4; (2) D 199.4 mi. by computation, 199.3 mi. by traverse table.

1004a. A ship steams as follows: course 359°, distance 28.8 miles; course 006°, distance 16.4 miles; course 266°, distance 4.9 miles; course 144°, distance 3.1 miles; course 333°, distance 35.8 miles; course 280°, distance 19.3 miles.

Required.—(1) Course, (2) distance, by traverse sailing.

Answers.—(1) C 334°4, (2) D 86.1 mi.

1005a. The 1530 DR position of a ship is lat. 44°36′3N, long. 31°18′3W. The ship is on course 270°, speed 17 knots.

Required.—The 2000 DR position, by parallel sailing.

Answer.—2000 DR: L 44°36′3N, λ 33°05′7W.

1005b. The captain of the ship of problem 1005a desires to change course when the ship arrives at long. 38°00′0W.

Required.—Estimated time of arrival (ETA) at the turning point, by parallel sailing.

Answer.—ETA 0819 the following day.

1006a. A vessel steams 263.3 miles on course 340° from lat. 16°32′.2S, long. 1°04′.4E.

Required.—(1) Latitude and (2) longitude of the point of arrival, by middle-latitude sailing.

Answers.—By computation or traverse table: (1) L 12°24′.8S, (2) λ 0°28′.6W.

1006b. A vessel leaves lat. 45°00′.0N, long. 150°00′.0W and arrives at lat. 38°18′.7N, long. 137°14′.6W.

Required.—(1) Course made good, (2) distance made good, by middle-latitude sailing.

Answers.—(1) C 125°.1; (2) D 698.6 mi. by computation, 697.9 mi. by traverse table.

1006c. A vessel is at lat. 1°08′.3S, long. 175°24′.5E. It steams at 13.5 knots on course 075° for 22^h15^m. Twenty-four hours after that it is at lat. 0°06′.6S, long. 174°20′.0W.

Required.—(1) Latitude and (2) longitude of the point of arrival after 22^h15^m; (3) course and (4) distance made good during the last 24 hours of steaming; and (5) course and (6) distance made good over entire period, by middle-latitude sailing.

Answers.—(1) L 0°09′.5N by computation, 0°09′.4N by traverse table; (2) λ179°45′.3W; (3) C 092°.8; (4) D 325.7 mi. by computation, 338.3 mi. by traverse table; (5) C 084°.3; (6) D 618.5 mi. by computation, 625.6 mi. by traverse table.

1007a. A ship at lat. 33°53′.3S, long. 18°23′.1E, leaving Cape Town, heads for destination near Ambrose Light, lat. 40°27′.1N, long. 73°49′.4W.

Required.—(1) Course and (2) distance, by Mercator sailing.

Answers.—(1) C 310°.9; (2) D 6,811.5 mi. by computation, 6,812.8 mi. by traverse table. Compare these answers with those of problem 1010, the great-circle sailing solution between the same points.

1007b. A ship at lat. 15°03′.7N, long. 151°26′.8E steams 57.4 miles on course 035°.

Required.—(1) Latitude and (2) longitude of the point of arrival, by Mercator sailing.

Answers.—(1) L 15°50′.7N, λ 152°00′.7E.

1010. A ship leaves Cape Town bound for New York City. The captain decides to use great-circle sailing from lat. 33°53′.3S, long. 18°23′.1E (near Green Point Light) to near Ambrose Light, lat. 40°27′.1N, long. 73°49′.4W.

Required.—(1) The initial great-circle course.

(2) The great-circle distance.

(3) The latitude and longitude of both vertices.

(4) The distance from the point of departure to each vertex.

(5) The latitude and longitude of points on the great circle at longitude 15°E and at each 5° of longitude thereafter to longitude 70°W.

Answers.—(1) C 304°.5. (2) D 6,762.7 mi. (3) L_v46°49′.4S, λ_v69°18′.8E; L_v46°49′.4 N, λ_v 110°41′.2W. (4)D 2,407.5 mi. to eastern hemisphere vertex, 8,392.5 mi. to western hemisphere vertex. (5) L_1 33°53′.3S, λ_1 18°23′.1E (point of departure); L_x 31°52′.2S, λ_x 15°00′.0E; L_x 28°32′.5S, λ_x 10°00′.0E; L_x 24°47′.7S, λ_x 5°00′.0E; L_x 20°37′.8S, λ_x 0°00′.0; L_x 16°04′.5S, λ_x 5°00′.0W; L_x 11°10′.8S, λ_x10°00′.0W; L_x 6°01′.7S, λ_x 15°00′.0 W; L_x0°43′.9S, λ_x20°00′.0W; L_x 4°35′.0N, λ_x 25°00′.0W; L_x 9°47′.2N, λ_x 30°00′.0W; L_x 14°45′.7N, λ_x 35°00′.0W; L_x 19°25′.0N, λ_x 40°00′.0W; L_x 23°41′.5N, λ_x 45°00′.0W; L_x 27°33′.3N, λ_x 50°00′.0W; L_x 30°59′.8N, λ_x 55°00′.0W; L_x 34°01′.7N, λ_x 60°00′.0W; L_x 36°40′.1N, λ_x 65°00′.0W; L_x 38°56′.6N, λ_x 70°00′.0W; L_2 40°27′.1N, λ_x 73°49′.4W (destination).

1011. A ship is to steam from Valparaiso, Chile to Wellington, New Zealand. The captain wishes to use composite sailing from lat. 32°58′.0S, long. 71°41′.2W, off Punta Angeles Light, to lat. 42°00′.0S, long. 175°00′.0E, near Cape Palliser, limiting the maximum latitude to 50°S.

Required.—(1) The longitude at which the limiting parallel is reached.

(2) The longitude at which the limiting parallel should be left.

(3) The initial great-circle course.

(4) The total distance.

(5) The latitude and longitude of points along the great circles at intervals of 10° of DLo from the vertices.

Answers.—(1) λ_{v1} 128°42′.9W. (2) λ_{v2} 144°04′.3W. (3) C 230°.0. (4) D 5,024.6 mi. (5) L_1 32°58′.0S, λ_1 71°41′.2W (point of departure); L_x 37°27′.2S, λ_x 78°42′.9W; L_x 42°23′.6S, λ_x 88°42′.9W; L_x 45°54′.3S, λ_x 98°42′.9W; L_x 48°14′.2S, λ_x 108°42′.9W; L_x 49°34′.1S, λ_x 118°42′.9W; L_{v1} 50°00′.0S, λ_{v1} 128°42′.9W (first vertex); L_{v2} 50°00′.0S, λ_{v2} 144°04′.3W (second vertex); L_x 49°34′.1S, λ_x 154°04′.3W; L_x 48°14′.2S, λ_x 164°04′.3W; L_x 45°54′.3S, λ_x 174°04′.3W; L_x 42°23′.6S, λ_x 175°55′.7E; L_2 42°00′.0S, λ_2 175°00′.0E (destination).

CHAPTER XI

TIDE AND CURRENT PREDICTIONS

1101. Tidal effects.—The daily rise and fall of the **tide,** with its attendant flood and ebb of **tidal current,** is familiar to every mariner. He is aware, also, that at **high water** and **low water** the depth of water is momentarily constant, a condition called **stand.** Similarly, there is a moment of **slack water** as a tidal current reverses direction. As a general rule, the *change* in height or the current *speed* is at first very slow, increasing to a maximum about midway between the two extremes, and then decreasing again. If plotted against time, the height of tide or speed of a tidal current takes the general form of a sine curve. Sample curves, and more complete information about causes, types, and features of tides and tidal currents, are given in volume I. Ocean (nontidal) currents are also discussed in volume I. The present chapter is concerned primarily with the application of tides and currents to piloting, and predicting the tidal conditions that might be encountered at any given time.

Although tides and tidal currents are caused by the same phenomena, the time relationship between them varies considerably from place to place. For instance, if an estuary has a wide entrance and does not extend far inland, the time of maximum speed of current occurs at about the mid time between high water and low water. However, if an extensive tidal basin is connected to the sea by a small opening, the maximum current may occur at about the time of high water or low water outside the basin, when the difference in height is maximum.

The *height of tide* should not be confused with *depth of water*. For reckoning tides a reference level is selected. Soundings shown on the largest scale charts are the vertical distances from this level to the bottom. At any time the actual depth is this charted depth *plus* the height of tide. In most places the reference level is some form of low water. But all low waters at a place are not the same height, and the selected reference level is seldom the *lowest* tide that occurs at the place. When lower tides occur, these are indicated by a negative sign. Thus, at a spot where the charted depth is 15 feet, the actual depth is 15 feet plus height of tide. When the tide is three feet, the depth is $15+3=18$ feet. When it is $(-)$ 1 foot, the depth is $15-1=14$ feet. It is well to remember that *the actual depth can be less than the charted depth.* In an area where there is a considerable **range of tide** (the difference between high water and low water), the height of tide might be an important consideration in using soundings to assist in determining position, or whether the vessel is in safe water.

One should remember that heights given in the tide tables are *predictions,* and that when conditions vary considerably from those used in making the predictions, the heights shown may be considerably in error. Heights lower than predicted are particularly to be anticipated when the atmospheric pressure is higher than normal, or when there is a persistent strong offshore wind. Along coasts where there is a large inequality between the two high or two low tides during a tidal day the height predictions are less reliable than elsewhere.

The current encountered in pilot waters is due primarily to tidal action, but other causes are sometimes present. The tidal current tables give the best prediction of total current, regardless of cause. The predictions for a river may be considerably

in error following heavy rains or a drought. The effect of current is to alter the course and speed made good over the bottom. Due to the configuration of land (or shoal areas) and water, the set and drift may vary considerably over different parts of a harbor. Since this is generally an area in which small errors in position of a vessel are of considerable importance to its safety, a knowledge of predicted currents can be critical, particularly if the visibility is reduced by fog, snow, etc. If the vessel is proceeding at reduced speed, the effect of current with respect to distance traveled is greater than normal. Strong currents are particularly to be anticipated in narrow passages connecting larger bodies of water. Currents of more than five knots are encountered from time to time in the Golden Gate at San Francisco. Currents of more than 13 knots sometimes occur at Seymour Narrows, British Columbia.

In straight portions of rivers and channels the strongest currents usually occur in the middle, but in curved portions the swiftest currents (and deepest water) usually occur near the outer edge of the curve. Countercurrents and eddies may occur on either side of the main current of a river or narrow passage, especially near obstructions and in bights.

In general, the range of tide and the speed of tidal current are at a minimum upon the open ocean or along straight coasts. The greatest tidal effects are usually encountered in rivers, bays, harbors, inlets, bights, etc. A vessel proceeding along a coast can be expected to encounter stronger sets toward or away from the shore while passing an indentation than when the coast is straight.

1102. Predictions of tides and currents to be expected at various places are published annually by the National Ocean Survey. These are supplemented by twelve sets of **Tidal Current Charts,** each set consisting of 12 charts, one for each hour of the tidal cycle. On these charts the set of the current at various places in the area is shown by arrows, and the drift by numbers. Since these are *average* conditions, they indicate in a general way the tidal conditions on any day and during any year. They are designed to be used with the tidal current tables (except those for New York Harbor, and Narragansett Bay, which are used with the tide tables). These charts are available for Boston Harbor, Narragansett Bay to Nantucket Sound, Narragansett Bay, Block Island Sound and Eastern Long Island Sound, Long Island Sound and Block Island Sound, New York Harbor, Delaware Bay and River, upper Chesapeake Bay, Charleston Harbor, San Francisco Bay, Puget Sound (northern part), and Puget Sound (southern part). Current arrows are sometimes shown on nautical charts. These represent average conditions and should not be considered reliable predictions of the conditions to be encountered at any given time. When a strong current sets over an irregular bottom, or meets an opposing current, ripples may occur on the surface. These are called **tide rips.** Areas where they occur frequently are shown on charts.

Usually, the mariner obtains tidal information from tide and tidal current tables. However, if these are not available, or if they do not include information at a desired place, the mariner may be able to obtain locally the **mean high water lunitidal interval** or the **high water full and change.** The approximate *time* of high water can be found by adding either interval to the time of transit (either upper or lower) of the moon (art. 733). Low water occurs approximately ¼ tidal day (about 6^h12^m) before and after the time of high water. The actual interval varies somewhat from day to day, but approximate results can be obtained in this manner. Similar information for tidal currents (**lunicurrent interval**) is seldom available.

1103. Tide tables for various parts of the world are published in four volumes by the National Ocean Survey. Each volume is arranged as follows:

Table 1 contains a complete list of the predicted times and heights of the tide for each day of the year at a number of places designated as **reference stations.**

Table 2 gives differences and ratios which can be used to modify the tidal information for the reference stations to make it applicable to a relatively large number of **subordinate stations.**

Table 3 provides information for use in finding the approximate height of the tide at any time between high water and low water.

Table 4 is a sunrise-sunset table at five-day intervals for various latitudes from 76°N to 60°S (40°S in one volume).

Table 5 provides an adjustment to convert the local mean time of table 4 to zone or standard time.

Table 6 (two volumes only) gives the zone time of moonrise and moonset for each day of the year at certain selected places.

Certain astronomical data are contained on the inside back cover of each volume.

Extracts from tables 1, 2, and 3 for the East Coast of North and South America are given in appendix L.

1104. Tide predictions for reference stations.—The first page of appendix L is the table 1 daily predictions for New York (The Battery) for the first quarter of 1975. As indicated at the bottom of the page, times are for Eastern Standard Time (+5 zone, time meridian 75°W). Daylight saving time is not used. Times are given on the 24-hour basis. The tidal reference level for this station is mean low water.

For each day, the date and day of week are given, and the time and height of each high and low water are given in chronological order. Although high and low waters are not labeled as such, they can be distinguished by the relative heights given immediately to the right of the times. Since *two* high tides and *two* low tides occur each tidal day, the type of tide at this place is *semidiurnal*. The *tidal* day being longer than the *civil* day (because of the revolution of the moon eastward around the earth), any given tide occurs *later* from day to day. Thus, on Saturday, March 29, 1975, the first tide that occurs is the lower low water (−1.2 feet at 0334). The following high water (lower high water) is 4.9 feet above the reference level (a 6.1 foot rise from the preceding low water), and occurs at 0942. This is followed by the higher low water (−0.9 feet) at 1547, and then the higher high water of 5.5 feet at 2206. The cycle is repeated on the following day with variations in height, and later times.

Because of later times of corresponding tides from day to day, certain days have only one high water or only one low water. Thus, on January 17 high tides occur at 1120 and 2357. The next following high tides are at 1154 on January 18 and 0029 on January 19. Thus, only one high tide occurs on January 18, the previous one being shortly before midnight on the seventeenth, and the next one occuring early in the morning of the nineteenth, as shown.

1105. Tide predictions for subordinate stations.—The second page of appendix L is a page of table 2 of the tide tables. For each subordinate station listed, the following information is given:

Number. The stations are listed in geographical order and given consecutive numbers. At the end of each volume an alphabetical listing is given, and for each entry the consecutive number is shown, to assist in finding the entry in table 2.

Place. The list of places includes both subordinate and reference stations, the latter being given in bold type.

Position. The approximate latitude and longitude are given to assist in locating the station. The latitude is north or south, and the longitude east or west, depending upon the letters (N, S, E, W) next *above* the entry. These may not be the same as those at the *top* of the column.

Differences. The differences are to be applied to the predictions for the reference station shown in bold capitals next *above* the entry on the page. Time and height differ-

ences are given separately for high and low waters. Where differences are omitted, they are either unreliable or unknown.

The time difference is the number of hours and minutes to be applied to the time at the reference station to find the time of the corresponding tide at the subordinate station. This interval is added if preceded by a plus sign (+), and subtracted if preceded by a minus sign (−). The results obtained by the application of the time differences will be in the zone time of the time meridian shown directly above the difference for the subordinate station. Special conditions occurring at a few stations are indicated by footnotes on the applicable pages. In some instances, the corresponding tide falls on a different date at reference and subordinate stations.

Height differences are shown in a variety of ways. For most entries separate height differences in feet are given for high water and low water. These are applied to the height given for the reference station. In many cases a *ratio* is given for either high water or low water, or both. The height at the reference station is multiplied by this ratio to find the height at the subordinate station. For a few stations, *both* a ratio and difference are given. In this case the height at the reference station is first multiplied by the ratio, and the difference is then applied. An example is given in each volume of tide tables. Special conditions are indicated in the table or by footnote. Thus, a footnote on the second page of appendix L indicates that "Values for the Hudson River above George Washington Bridge are based upon averages for the six months May to October, when the fresh-water discharge is a minimum."

Ranges. Various ranges are given, as indicated in the tables. In each case this is the difference in height between high water and low water for the tides indicated.

Example.—List chronologically the times and heights of all tides at Yonkers, (No. 1531) on January 2, 1975.

Solution.—

Date	January 2, 1975
Subordinate station	Yonkers
Reference station	New York
High water time difference	(+) 1^h09^m
Low water time difference	(+) 1^h10^m
High water height difference	(−) 0.8 ft.
Low water height difference	0.0 ft.

	New York		*Yonkers*	
HW	2321 (1st)	4.6 ft.	0030	3.8 ft.
LW	0516	(−) 0.6 ft.	0626	(−) 0.6 ft.
HW	1138	4.9 ft.	1247	4.1 ft.
LW	1749	(−) 0.9 ft.	1859	(−) 0.9 ft.

1106. Finding height of tide at any time.—Table 3 of the tide tables provides means for determining the approximate height of tide at any time. It is based upon the assumption that a plot of height versus time is a sine curve (art. 140). Instructions for use of the table are given in a footnote below the table, which is reproduced in appendix L.

Example 1.—Find the height of tide at Yonkers (No. 1531) at 1000 on January 2, 1975.

Solution.—The given time is between the low water at 0626 and the high water at 1247 (example of art. 1105). Therefore, the tide is rising. The duration of rise is $1247-0626=6^h21^m$. The range of tide is $4.1-(-0.6)=4.7$ feet. The given time is

2^h47^m *before* high water, the nearest tide. Enter the upper part of the table with duration of rise 6^h20^m (the nearest tabulated value to 6^h21^m), and follow the line horizontally to 2^h45^m (the nearest tabulated value to 2^h47^m). Follow this column vertically downward to the entry 1.8 feet in the line for a range of tide of 4.5 feet (the nearest tabulated value to 4.7 feet). This is the correction to be applied to the nearest tide. Since the nearest tide is high water, subtract 1.8 from 4.1 feet. The answer, 2.3 feet, is the height of tide at the given time.

Answer.—Ht. of tide at 1000, 2.3 ft.

Interpolation in this table is not considered justified.

It may be desired to know at what time a given depth of water will occur. In this case, the problem is solved in reverse.

Example 2.—The captain of a vessel drawing 22 feet wishes to pass over a temporary obstruction near Days Point, Weehawken (No. 1521), having a charted depth of 21 feet, passage to be made during the morning of January 31, 1975.

Required.—The earliest time after 0800 that this passage can be made, allowing a safety margin of two feet.

Solution.—The least acceptable depth of water is 24 feet, which is three feet more than the charted depth. Therefore, the height of tide must be three feet or more. At the New York reference station a low tide of (−)0.9 foot occurs at 0459, followed by a high tide of 4.9 feet at 1120. At Days Point the corresponding low tide is (−)0.9 foot at 0522, and the high tide is 4.6 feet at 1144. The duration of rise is 6^h22^m, and the range of tide is 5.5 feet. The least acceptable tide is 3.0 feet, or 1.6 feet less than high tide. Enter the *lower* part of table 3 with range 5.5 feet and follow the horizontal line until 1.6 feet is reached. Follow this column vertically *upward* until the value of 2^h19^m is reached on the line for a duration of 6^h20^m (the nearest tabulated value to 6^h22^m). The minimum depth will occur about 2^h19^m *before* high water or at about 0925.

Answer.—A depth of 24 feet occurs at 0925.

If the range of tide is more than 20 feet, *half* the range (*one third* if the range is greater than 40 feet) is used to enter table 3, and the correction to height is *doubled* (*trebled* if one third is used).

A diagram for a graphical solution is given in figure 1106. Eye interpolation can be used if desired. The steps in this solution are as follows:

1. Enter the upper graph with the duration of rise or fall. This is represented by a horizontal line.
2. Find the intersection of this line and the curve representing the interval from the nearest *low* water (point *A*).
3. From *A*, follow a vertical line to the sine curve of the lower diagram (point *B*).
4. From *B*, follow horizontally to the vertical line representing the range of tide (point *C*).
5. Using *C*, read the correction from the series of curves.
6. Add (algebraically) the correction of step 5 to the *low* water height, to find the height at the given time.

The problem illustrated in figure 1106 is similar to that of example 1 given above. The duration of rise is 6^h25^m, and the interval from *low* water is 5^h23^m. The range of tide is 6.1 feet. The correction (by interpolation) is 5.7 feet. If the height of the preceding low tide is (−)0.2 foot, the height of tide at the given time is (−)0.2+5.7=5.5 feet. To solve example 2 by the graph, enter the lower graph and find the intersection of the vertical line representing 5.5 feet and the curve representing 3.9 feet (the minimum acceptable height above low water). From this point follow horizontally to the sine curve, and then vertically to the horizontal line in the upper figure representing the duration of rise of 6^h22^m. From the curve, determine the interval 4^h00^m. The earliest time is about 4^h00^m *after* low water, or at about 0922.

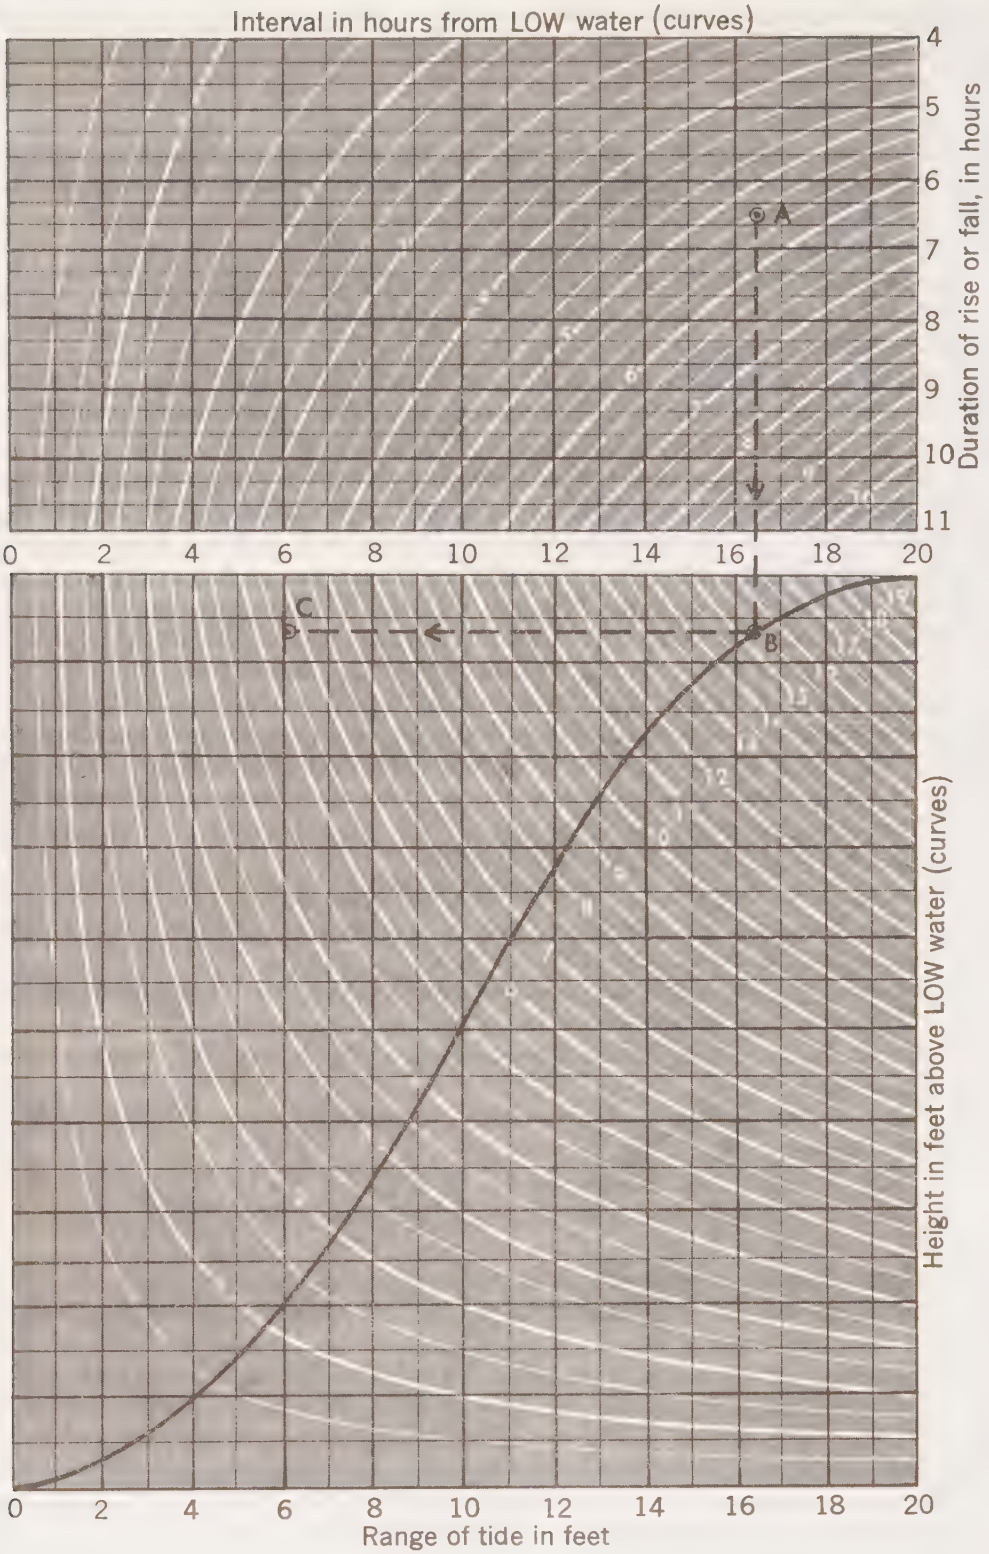

FIGURE 1106.—Graphical solution for height of tide at any time.

1107. Tidal current tables are somewhat similar to tide tables, but the coverage is less extensive, being given in two volumes. Each volume is arranged as follows:

Table 1 contains a complete list of predicted times of maximum currents and slack, with the velocity (speed) of the maximum currents, for a number of reference stations.

Table 2 gives differences, ratios, and other information related to a relatively large number of subordinate stations.

Table 3 provides information for use in finding the speed of the current at any time between tabulated entries in tables 1 and 2.

Table 4 gives the number of minutes the current does not exceed stated amounts, for various maximum speeds.

Table 5 (Atlantic Coast of North America only) gives information on rotary tidal currents.

Each volume contains additional useful information related to currents. Extracts from the tables for the Atlantic Coast of North America are given in appendix M.

1108. Tidal current predictions for reference stations.—The extracts of appendix M are for The Narrows, New York Harbor. Times are given on the 24-hour basis, for meridian 75° W. *Daylight saving time is not used.*

For each day, the date and day of week are given, with complete current information. Since the cycle is repeated twice each tidal day, currents at this place are semidiurnal. On most days there are four slack waters and four maximum currents, two of them floods (F) and two of them ebbs (E). However, since the tidal day is longer than the civil day, the corresponding condition occurs later from day to day, and on certain days there are only three slack waters or three maximum currents. At some places, the current on some days runs maximum flood twice, but ebb only once, a minimum flood occurring in place of the second ebb. The tables show this information.

As indicated by appendix M, the sequence of currents at The Narrows on Monday February 3, 1975, is as follows:

0000 Flood current, 5^m after maximum velocity (speed).
0305 Slack, ebb begins.
0621 Maximum ebb of 2.0 knots, setting 160°.
1005 Slack, flood begins.
1222 Maximum flood of 1.5 knots, setting 340°.
1516 Slack, ebb begins.
1839 Maximum ebb of 1.9 knots, setting 160°.
2216 Slack, flood begins.
2400 Flood current, 56^m before maximum velocity (speed).

Only one maximum flood occurs on this day, the previous one having occurred 5 minutes before the day began, and the following one predicted for 56 minutes after the day ends.

1109. Tidal current predictions for subordinate stations.—For each subordinate station listed in table 2 of the tidal current tables, the following information is given:

Number. The stations are listed in geographical order and given consecutive numbers, as in the tide tables (art. 1105). At the end of each volume an alphabetical listing is given, and for each entry the consecutive number is shown, to assist in finding the entry in table 2.

Place. The list of places includes both subordinate and reference stations, the latter being given in **bold type.**

Position. The approximate latitude and longitude are given to assist in locating the station. The latitude is north or south and the longitude east or west as indicated by the letters (N, S, E, W) next *above* the entry. The current given is for the center of the channel unless another location is indicated by the station name.

Time difference. Two time differences are tabulated. One is the number of hours and minutes to be applied to the tabulated times of slack water at the reference station to find the times of slack waters at the subordinate station. The other time difference is applied to the times of maximum current at the reference station to find the times of the corresponding maximum current at the subordinate station. The intervals, which are added or subtracted in accordance with their signs, include any difference in time between the two stations, so that the answer is correct for the standard time of the subordinate station. Limited application and special conditions are indicated by footnotes.

Velocity (speed) ratios. Speed of the current at the subordinate station is found by multiplying the speed at the reference station by the tabulated ratio. Separate ratios may be given for flood and ebb currents. Special conditions are indicated by footnotes.

As indicated in appendix M, the currents at The Battery (No. 2375) can be found by *adding* 1^h30^m for slack water and 1^h35^m for maximum current to the times for The Narrows, and multiplying flood currents by 0.9 and ebb currents by 1.2. Applying these to the values for Monday, February 3, 1975, the sequence is as follows:

0000 Flood current, 1^h30^m before maximum velocity (speed).
0130 Maximum flood of 1.8 knots, setting 015°.
0435 Slack, ebb begins.
0756 Maximum ebb of 2.4 knots, setting 195°.
1135 Slack, flood begins.
1357 Maximum flood of 1.4 knots, setting 015°.
1646 Slack, ebb begins.
2014 Maximum ebb of 2.3 knots, setting 195°.
2346 Slack, flood begins.
2400 Flood current, 14^m after slack.

1110. Finding speed of tidal current at any time.—Table 3 of the tidal current tables provides means for determining the approximate velocity (speed) at any time. Instructions for its use are given below the table, which is reproduced in appendix M.

Example 1.—Find the speed of the current at The Battery at 1500 on February 3, 1975.

Solution.—The given time is between the maximum flood of 1.4 knots at 1357 and the slack at 1646 (art. 1109). The interval between slack and maximum current (1646 −1357) is 2^h49^m. The interval between slack and the desired time (1646−1500) is 1^h46^m. Enter the table (A) with 2^h40^m at the top, and 1^h40^m at the left side (the nearest tabulated values to 2^h49^m and 1^h46^m, respectively), and find the factor 0.8 in the body of the table. The approximate speed at 1500 is $0.8\times1.4=1.1$ knots, and it is flooding.

Answer.—Speed 1.1 kn.

It may be desired to determine the period during which the current is less (or greater) than a given amount. Table 4 of the tidal current tables can be used to determine the period during which the speed does not exceed 0.5 knot. For greater speeds, and for more accurate results under some conditions, table 3 of the tidal current tables can be used, solving by reversing the process used in example 1.

Example 2.—During what period on the evening of February 3, 1975, does the ebb current equal or exceed 1.0 knot at The Battery?

Solution.—The maximum ebb of 2.3 knots occurs at 2014. This is preceded by a slack at 1646, and followed by the next slack at 2346. The interval between the earlier slack and the maximum ebb is 3^h28^m, and the interval between the ebb and following slack is 3^h32^m. The desired factor is $\frac{1.0}{2.3}=0.4$. Enter table A with 3^h20^m (the nearest tabulated value to 3^h28^m) at the top, and follow down the column to 0.4 (midway

between 0.3 and 0.5). At the left margin the interval between slack and the desired time is found to be 0^h50^m (midway between 0^h40^m and 1^h00^m). Therefore, the current becomes 1.0 knot at $1646+0^h50^m=1736$. Next, enter table A with 3^h40^m (the nearest tabulated value to 3^h32^m) at the top, and follow down the column to 0.4. Follow this line to the left margin, where the interval between slack and desired time is found to be 1^h00^m. Therefore, the current is 1.0 knot or greater until $2346-1^h00^m=2246$. If the two intervals between maximum current and slack were nearest the same 20^m interval, table A would have to be entered only once.

Answer.—The speed equals or exceeds 1.0 knot between 1736 and 2246.

1111. Current diagrams.—A current diagram is a graph showing the speed of the current along a channel at different stages of the tidal current cycle. The current tables include such diagrams for Boston Harbor; Vineyard and Nantucket Sounds (one diagram); East River, New York; New York Harbor; Delaware Bay and River (one diagram); Chesapeake Bay; South San Francisco Bay; and North San Francisco Bay. The diagram for New York Harbor is reproduced in appendix M.

On this diagram each vertical line represents a given instant identified in terms of the number of hours before or after slack *at The Narrows*. Each horizontal line represents a distance from Ambrose Channel Entrance, measured along the usually-traveled route. The names along the left margin are placed at the correct distances from Ambrose Channel Entrance. The current is for the center of the channel opposite these points. The intersection of any vertical line with any horizontal line represents a given moment in the current cycle at a given place in the channel. If this intersection is in a shaded area, the current is flooding; if in an unshaded area, it is ebbing. The speed in knots can be found by interpolation (if necessary) between the numbers given in the body of the diagram. The given values are *averages*. To find the value at any given time, multiply the speed found from the diagram by the ratio of *maximum speed of the current involved* to the *maximum shown on the diagram*, both values being taken for The Narrows. If the diurnal inequality is large, the accuracy can be improved by altering the width of the shaded area to fit conditions. The diagram covers 1½ current cycles, so that the right-hand third is a duplication of the left-hand third.

If the current for a single station is desired, table 1 or 2 should be used. The current diagrams are intended for use in either of two ways: First, to determine a favorable time for passage through the channel. Second, to find the average current to be expected during any passage through the channel. For both of these uses a number of "speed lines" are provided. When the appropriate line is transferred to the correct part of the diagram, the current to be encountered during passage is indicated along the line.

Example.—During the morning of January 3, 1975, a ship is to leave Pier 83 at W. 42nd St., and proceed down the bay at ten knots.

Required.—(1) Time to get underway to take maximum advantage of a favorable current, allowing 15 minutes to reach mid channel.

(2) Average speed over the bottom during passage down the bay.

Solution.—(1) Transfer the line (slope) for ten knots southbound to the diagram, locating it so that it is centered on the unshaded ebb current section between W. 42nd St. and Ambrose Channel Entrance. This line crosses a horizontal line through W. 42nd St. about one-half of the distance between the vertical lines representing three and two hours, respectively, after ebb begins at The Narrows. The setting is not critical. Any time within about half an hour of the correct time will result in about the same current. Between the points involved, the entire speed line is in the ebb current area.

(2) Table 1 indicates that on the morning of January 3 ebb begins at The Narrows at 0132. Two hours twenty-eight minutes after ebb begins, the time is 0400. Therefore,

the ship should reach mid channel at 0400. It should get underway 15 minutes earlier, at 0345.

(3) To find the average current, determine the current at intervals (as every two miles), add, and divide by the number of entries.

Distance	*Current*
18	1.2
16	1.4
14	1.9
12	1.5
10	2.0
8	1.9
6	1.3
4	1.2
2	1.4
0	1.2
sum	15.0

The sum of 15.0 is for ten entries. The average is therefore $15.0 \div 10 = 1.5$ knots.

(4) This value of current is correct only if the ebb current is an average one. From table 1 the maximum ebb involved is 2.2 knots. From the diagram the maximum value at The Narrows is 2.0 knots. Therefore, the average current found in step (3) should be increased by the ratio $2.2 \div 2.0 = 1.1$. The average for the run is therefore $1.5 \times 1.1 = 1.6$ knots. Speed over the bottom is $10 + 1.6 = 11.6$ knots.

Answers.—(1) T 0345, (2) S 11.6 kn.

In the example, an ebb current is carried throughout the run. If the transferred speed line had been partly in a flood current area, all ebb currents (those increasing the ship's speed) should be given a positive sign (+), and all flood currents a negative sign (−). A separate ratio should be determined for each current (flood or ebb), and applied to the entries for that current. In Chesapeake Bay it is not unusual for an outbound vessel to encounter three or even four separate currents during passage down the bay. Under the latter condition, it is good practice to multiply *each* current taken from the diagram by the ratio for the current involved.

If the time of starting the passage is fixed, and the current during passage is desired, the starting time is identified in terms of the reference tidal cycle. The speed line is then drawn through the intersection of this vertical time line and the horizontal line through the place. The average current is then determined in the same manner as when the speed line is located as described above.

Problems

1102. The mean high water lunitidal interval at a certain port is 2^h17^m.

Required.—The approximate times of each high and low water on a day when the moon transits the local meridian at 1146.

Answers.—HW at 0139 and 1403, LW at 0751 and 2015.

1104. List chronologically the times and heights of all tides at New York (The Battery) on February 11, 1975.

Answer.—

Time	*Tide*	*Height*
0222	LW	(−) 0.4 ft.
0829	HW	4.6 ft.
1449	LW	(−) 0.6 ft.
2053	HW	4.2 ft.

1105. List chronologically the times and heights of all tides at Castle Point, Hoboken, N.J. (No. 1519) on March 18, 1975.

Answer.—

Time	*Tide*	*Height*
0533	LW	0.2 ft.
1141	HW	3.5 ft.
1724	LW	0.3 ft.
0003	HW	4.1 ft.

1106a. Find the height of tide at Union Stock Yards, New York (No. 1523) at 0600 on February 6, 1975.

Answer.—Ht. of tide at 0600, 3.8 ft.

1106b. The captain of a vessel drawing 24 feet wishes to pass over a temporary obstruction near Bayonne, N.J. (No. 1505) having a charted depth of 23 feet, passage to be made during the afternoon of March 5, 1975.

Required.—The earliest and latest times that the passage can be made, allowing a safety margin of two feet.

Answers.—Earliest time 1316, latest time 1531.

1108. Determine the sequence of currents at The Narrows on January 15, 1975.

Answer.—

0000 Ebb current, 42^{m} after slack.
0231 Maximum ebb of 1.9 knots.
0557 Slack, flood begins.
0822 Maximum flood of 1.7 knots.
1137 Slack, ebb begins.
1455 Maximum ebb of 2.1 knots.
1836 Slack, flood begins.
2051 Maximum flood of 1.5 knots.
2400 Flood current, 2^{m} before slack.

1109. Determine the sequence of currents at Ambrose Channel Entrance (No. 2310) on January 12, 1975.

Answer.—

0000 Ebb current, 42^{m} after maximum velocity (speed).
0241 Slack, flood begins.
0533 Maximum flood of 2.0 knots, setting 310°.
0828 Slack, ebb begins.
1155 Maximum ebb of 2.5 knots.
1527 Slack, flood begins.
1801 Maximum flood of 1.5 knots, setting 310°.
2040 Slack, ebb begins.
2400 Ebb current, 3^{m} before maximum velocity (speed).

1110a. Find the speed of the current at Bear Mountain Bridge (No. 2445) at 0900 on February 19, 1975.

Answer.—Speed 0.8 kn.

1110b. At about what time during the afternoon of February 3, 1975, does the flood current northwest of The Battery (No. 2375) reach a speed of 1.0 knot?

Answer.—T 1245.

1111. A vessel arrives at Ambrose Channel Entrance two hours after flood begins at The Narrows on the morning of February 16, 1975.

Required.—(1) The speed through the water required to take fullest advantage of the flood tide in steaming to Chelsea Docks.

(2) The average current to be expected.
(3) Estimated time of arrival off Chelsea Docks.
Answers.—(1) S 9 kn., (2) S 1.4 kn., (3) ETA 1035.

CHAPTER XII

DISTANCE CALCULATIONS

1201. Introduction.—If a vessel is known to be a certain distance from an identified point on the chart, it must be somewhere on a circle with that point as the center and the distance as radius.

Distances are obtained by radar, range finder, stadimeter, vertical sextant angles (table 9), etc.

1202. Distance, speed, and time are related by the formula

$$\text{distance} = \text{speed} \times \text{time}.$$

Therefore, if any two of the three quantities are known, the third can be found. The units, of course, must be consistent. Thus, if speed is measured in knots, and time in hours, the answer is in nautical miles. Similarly, if distance is measured in yards, and time in minutes, the answer is in yards per minute.

Table 19 is a speed, time, and distance table which supplies one of the three values if the other two are known. It is intended primarily for use in finding the distance steamed in a given time at a known speed. Table 18 is for use in determining speed by measuring the time needed to steam exactly one mile.

Speed is customarily expressed in knots (art. 405), or for some purposes, in kilometers per hour, or yards or feet per minute. For short distances, a nautical mile can be considered equal to 2,000 yards or 6,000 feet. This is a useful relationship because $\frac{6{,}000 \text{ feet}}{60 \text{ minutes}} = 100$ feet per minute. Thus, speed in knots is equal approximately to hundreds of feet per minute or, hundreds of yards per 3-minute interval.

The **Logarithmic Time-Speed-Distance Nomogram** is frequently used for the solution of the formula distance = speed × time. The upper scale is graduated logarithmically in minutes of time; the middle scale is graduated logarithmically in miles (sometimes both miles and yards); and the lower scale is graduated logarithmically in knots. By marking the values of two known terms on their respective scales and connecting such marks by a straight line, the value of the third term is found at the intersection of this line with the remaining scale. Figure 1202a illustrates a solution for speed when a distance of 4 miles is traveled in 11 minutes.

Only one of the three scales is required to solve for time, speed, or distance if any two of the three values are known. Either of the three logarithmic scales may be used in the same manner as a slide rule (art. 115) for the addition or subtraction of logarithms of numbers. Because the upper scale is larger, its use for this purpose is preferred.

When using a single logarithmic scale for the solution of the basic formula with speed units in knots and distance units in miles or thousands of yards, either 60 or 30 has to be incorporated in the basic equation for proper cancellation of units.

Figure 1202a illustrates the use of the upper scale for finding the speed in knots when the time in minutes and the distance in miles are known. In this problem the time is 11 minutes and the distance is 4 miles. One point of a pair of dividers is set at the time in minutes, 11, and the second point at the distance in miles, 4. Without

changing the spread of the dividers or the right-left relationship, set the first point at 60. The second point will then indicate the speed in knots, 21.8. If the speed and time are known, place one point at 60 and the second point at the speed in knots, 21.8. Without changing the spread of the dividers or the right-left relationship, place the first point at the time in minutes, 11. The second point then will indicate the distance in miles, 4.

In the method described, there was no real requirement to maintain the right-left relationship of the points of the pair of dividers except to insure that for speeds of less than 60 knots the distance in miles is less than the time in minutes. If the speed is in excess of 60 knots, the distance in miles will always be numerically greater than the time in minutes.

If the distance is known in thousands of yards or if the distance is to be found in such units, a divider point is set at 30 rather than the 60 used with miles. If the speed is less than 30 knots in this application, the distance in thousands of yards will always be numerically less than the time in minutes. If the speed is in excess of 30 knots, the distance in thousands of yards will always be numerically greater than the time in minutes.

For speeds of less than 60 knots and when using a logarithmic scale which increases from left to right, the distance graduation always lies to the left of the time in minutes graduation; the speed in knots graduation always lies to the left of the 60 graduation.

The use of the single logarithmic scale is based upon the fundamental property of logarithmic scales that equal lengths along the scale represent equal values of ratios. For example if one has the ratio ½ and

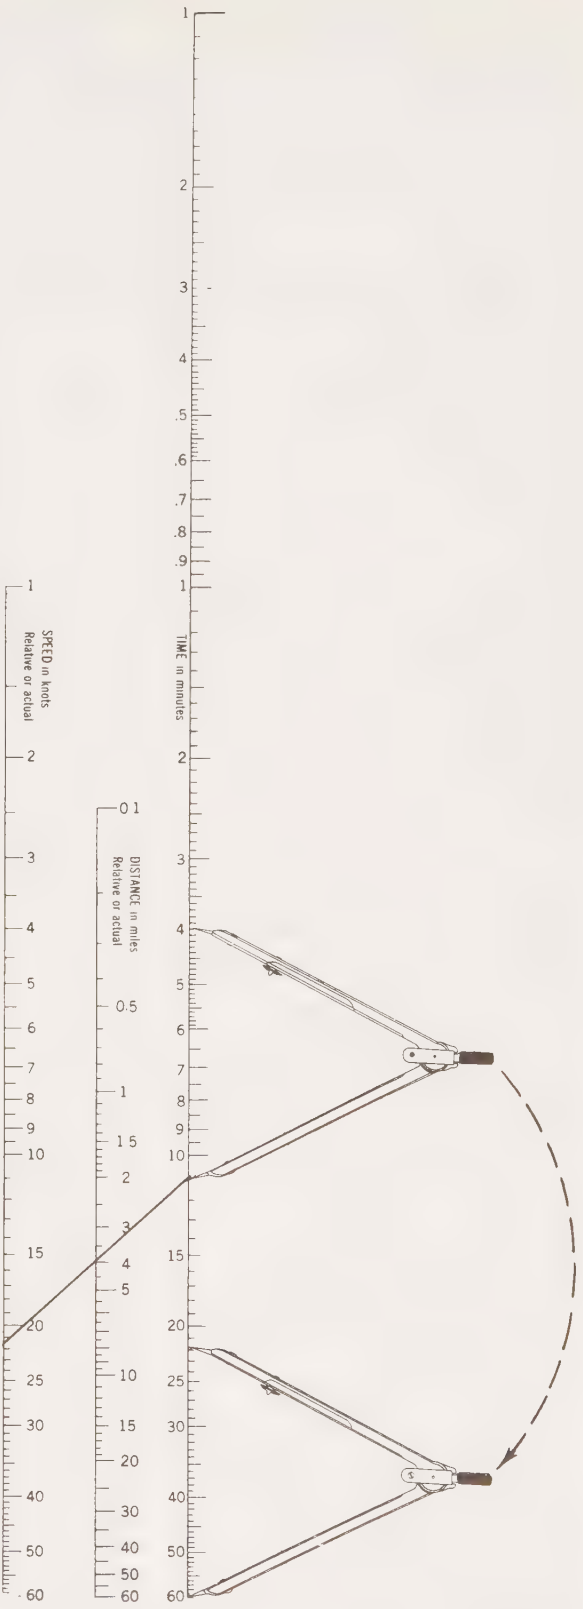

FIGURE 1202a.—Logarithmic time-speed-distance nomogram.

with the dividers measures the length between 1 and 2, he finds the same length between 2 and 4, 5.5 and 11.0, or any other two values one of which is half the other. In using the single logarithmic scale for the solution of a specific problem in which a ship travels 10 nautical miles in 20 minutes, the basic formula is rearranged as follows:

$$\text{Speed}=\frac{\text{Distance (nautical miles)}}{\text{Time (minutes)}}\times\frac{60 \text{ min.}}{1 \text{ hr.}}.$$

On substituting known numerical values and canceling units, the formula is rearranged further as:

$$\frac{\text{Speed (knots)}}{60}=\frac{10}{20}.$$

The ratio 10/20 has the same numerical value as the ratio Speed (knots)/60. Since each ratio has the same numerical value, the length as measured on the logarithmic scale between the distance in nautical miles (10) and the time in minutes (20) will be the same as the length between 60 and the speed in knots. Thus, on measuring the length between 10 and 20 and measuring the same length from 60 the speed is found to be 30 knots.

The solution of problems involving distance, speed, and time can easily be accomplished by means of a slide rule (art. 115). If the index of scale *C* is set opposite speed in knots on scale *D*, the distance in nautical miles appears on scale *D* opposite time in hours on scale *C*. If 60 of scale *C* is set opposite speed in knots on scale *D*, the distance covered in any number of *minutes* is shown on scale *D* opposite the minutes on scale *C*. Several circular slide rules particularly adapted for solution of distance, speed, and time problems have been devised. One of these, called the "Nautical Slide Rule" is shown in figure 1202b.

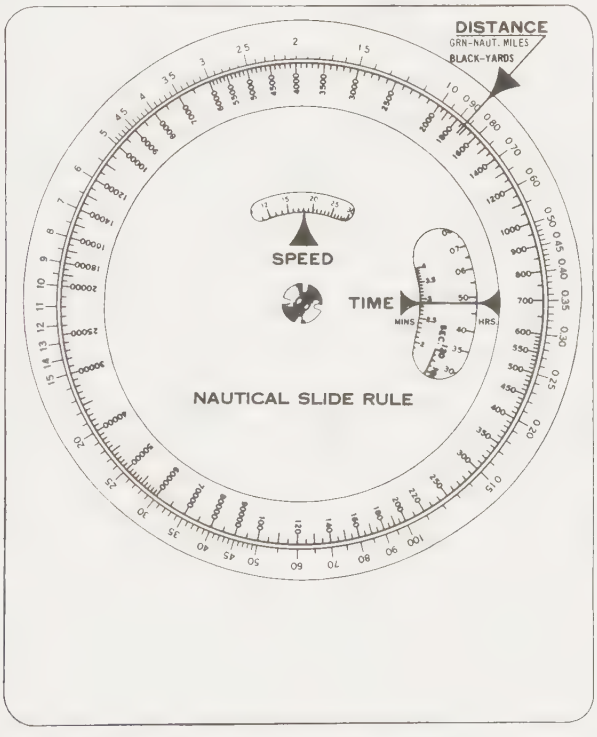

FIGURE 1202b.—The nautical slide rule.

1203. Distance by vertical angle.—If vertical sextant angles are used, measurement should be made from the top of the object to the visible sea horizon, if it is available, as shown in figure 1203a. If measurement is made to a water line not vertically below the top of the object, as shown in figure 1203b, a problem may be encountered because distance from table 9 is to the point vertically below the top of the object, while the distance used for entering table 22 to determine dip short of the horizon is to the water line. Generally, any differences in these two distances can be determined from the chart. This problem may, in some cases, be avoided by decreasing the height of eye sufficiently to bring the horizon between the observer and the object.

Example 1.—Using a sextant with an index error of (+)1′.0, the navigator measures the vertical angle between the visible horizon and the peak of a 520-foot hill beyond from a height of eye of 20 feet; the sextant altitude is 0°16′.3.

Required.—The distance to the point below the peak as indicated in figure 1203a.

Solution.—(1) Refer to the explanation of table 9 preceding the tables. Correct the sextant altitude for index error and dip only.

(2) Enter table 9 with the corrected vertical angle (0°11′.0) and the difference in feet between the height of the object and the height of eye of the observer (500 feet) as arguments and extract the distance to the hill (16.0 nautical miles).

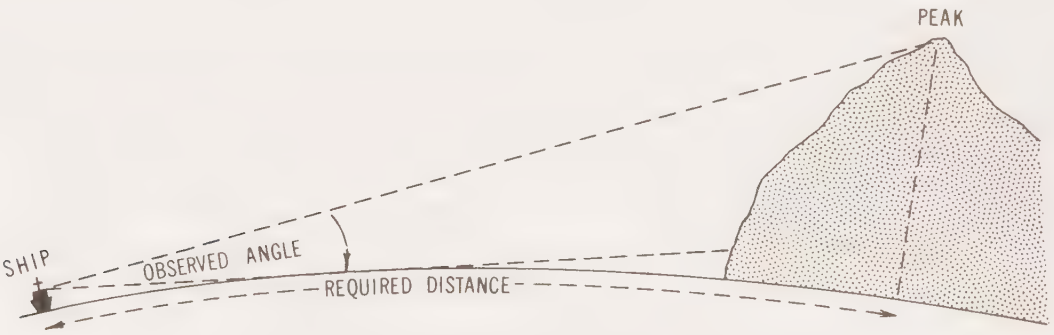

FIGURE 1203a.—Vertical angle above the visible horizon.

Example 2.—Using a sextant having an index error of (−)1′.0 the navigator measures the vertical angle between the top of a lighthouse 100 feet above sea level and the waterline below from a height of eye of 40 feet; the sextant altitude is 0°13′.3.

Required.—The distance to the lighthouse.

Solution.—(1) Refer to the explanations of tables 9 and 22 preceding the tables. Correct the sextant altitude for index error and dip of the sea short of the horizon only. The "dip short" correction is found by entering table 22 with the estimated distance (4.0 nautical miles) to the waterline below the lighthouse and the observer's height of eye (40 feet).

(2) Combine this correction (−7′.3) with the index correction (+1′.0) to find the corrected altitude (0°07′.0).

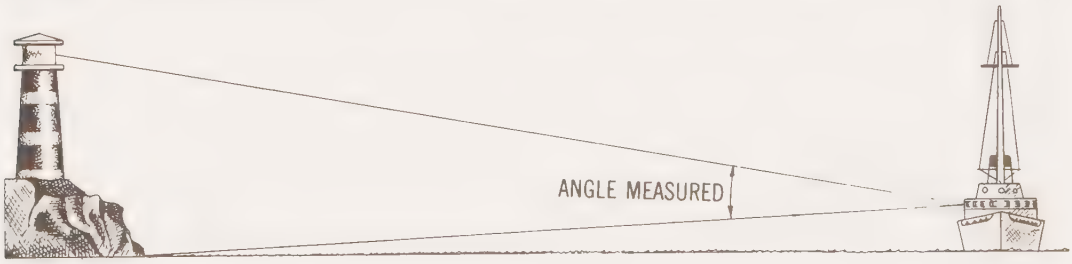

FIGURE 1203b.—Vertical angle between top of object and waterline at object.

(3) Enter table 9 with the corrected angle (0°07′.0) and the difference in feet between the elevation of the top of the lighthouse above sea level and the observer's height of eye (60 feet). The distance to the lighthouse is found as 3.9 nautical miles.

This procedure may require several approximations of distance by alternate entries of tables 9 and 22 until the same value is found twice.

1204. Distance of an object by two bearings.—A running fix can be obtained by utilizing the mathematical relationships involved. A ship steams past landmark *D* (fig. 1204). At any point *A* a bearing of *D* is observed and expressed as degrees right or left of the course (*a relative bearing if the ship is on course*). At some later time, at *B*, a second bearing of *D* is observed and expressed as before. At *C* the landmark is broad on the beam. The angles at *A*, *B*, and *C* are known, and also the distance run between points. The various triangles could be solved by trigonometry to find the distance from *D* at any bearing. Distance and bearing provide a fix.

Table 7 provides a quick and easy solution. The table is entered with the difference between the course and first bearing (angle *BAD* in fig. 1204) along the top of the table, and the difference between the course and second bearing (angle *CBD*) at the left of the table. For each pair of angles listed, two numbers are given. To find the distance from the landmark at the time of the second bearing (*BD*), multiply the distance run between bearings by the first number from table 7. To find the distance when the object is abeam (*CD*), multiply the distance run between *A* and *B* by the second number from the table. If the run between bearings is exactly one mile, the tabulated values are the distances sought.

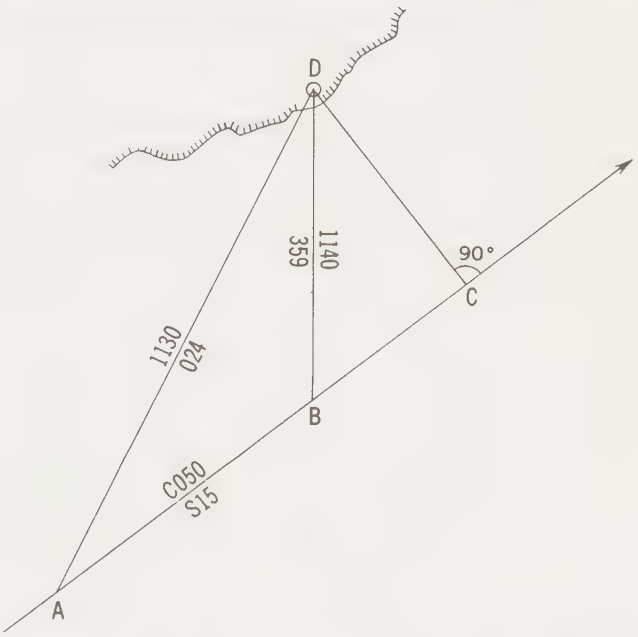

FIGURE 1204.—Triangles involved in a running fix.

Example.—A ship is steaming on course 050°, speed 15 knots. At 1130 a lighthouse bears 024°, and at 1140 it bears 359°

Required.—(1) Distance from the light at 1140.

(2) Distance from the light when it is broad on the port beam.

Solution (fig. 1204).—(1) The difference between the course and the first bearing (050°−024°) is 26°, and the difference between the course and the second bearing (050°+360°−359°) is 51°.

(2) From table 7 the two numbers (factors) are 1.04 and 0.81, found by interpolation.

(3) The distance run between bearings is 2.5 miles (10 minutes at 15 knots).

(4) The distance from the lighthouse at the time of the second bearing is 2.5× 1.04=2.6 miles.

(5) The distance from the lighthouse when it is broad on the beam is 2.5×0.81= 2.0 miles.

Answers.—(1) D 2.6 mi., (2) D 2.0 mi.

1205. Special cases.—There are certain special cases arising under the method of obtaining a running fix from two bearings and the intervening run which do not require the use of tables. Two of these cases arise when the multiplier is equal to unity, and the distance run is therefore equal to the distance from the object.

If the second difference (angle *CBD* of figure 1204) is double the first difference (angle *BAD*), triangle *BAD* is isosceles (art. 128) with equal angles at *A* and *D*. Therefore, side *AB* (the run) is equal to side *BD* (the distance off at the time of the second bearing). This is called **doubling the angle on the bow.** If the first angle is 45° and the second 90°, the distance run equals the distance when broad on the beam. These are called **bow and beam bearings.**

When the first bearing is 26½° from ahead, and the second 45°, the distance *at which the object will be passed abeam* will equal the run between bearings. This is true of any two such bearings whose natural cotangents differ by unity, and the following table is a collection of solutions of this relation in which the pairs of bearings are such that, when observed in succession from ahead upon the same fixed object, the distance run between the bearings will be equal to the distance of the fixed object when it bears abeam, *provided that a steady course has been steered, unaffected by current.* See figure 1205.

The marked pairs will probably be found the most convenient ones to use, as they involve whole degrees only. The use of the table may be found to be more convenient than the use of table 7, which covers all combinations of bearings in which the first bearing is taken when the object is 20° or more on the bow.

First	Second	First	Second	First	Second
°	°	°	°	°	°
20	29¾	28	48½	37	71¾
21	31¾	*29	51	38	74¼
*22	34	30	53¾	39	76¾
23	36¼	31	56¼	*40	79
24	38¾	*32	59	41	81¼
*25	41	33	61½	42	83½
26	43½	34	64¼	43	85¾
26½	45	35	66¾	*44	88
*27	46	36	69¼	*45	90

TABLE 1205.—Pairs of bearings whose natural cotangents differ by unity.

If bearings of the fixed object be taken at two (2) and four (4) points on the bow (22½° and 45°), seven-tenths (0.7) of the run between bearings will be the distance at which the point will be passed abeam. This is known as the **seven-tenths rule.**

From the combination of the seven-tenths rule and the 26½°–45° rule, there follows an interesting corollary, i.e., if bearings of an object at 22½° and 26½° on the bow be taken, then seven-thirds (⅞) of the distance run in the interval will be the distance when abeam.

If a bearing is taken when an object is two (2) points (22½°) forward of the beam, and the run until it bears abeam is measured, then its distance when abeam is seven-thirds (⅞) of the run. This rule, particularly, is only approximate.

In case the 45° bearing on the bow is lost, in order to find the distance abeam that the object is passed, note the time when the object bears 26½° forward of the beam, and again when it has the same bearing abaft the beam; the distance run in this interval is the distance of the object when it was abeam.

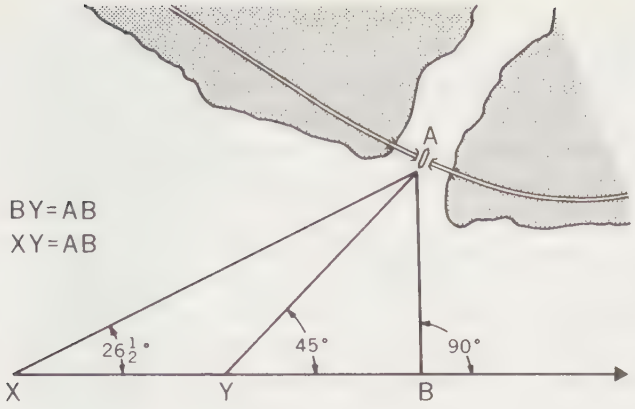

FIGURE 1205.—Special case.

1206. Range of lights.—Usually a navigator wants to know not only the identity of a light, but also the area in which he might reasonably expect to observe it. His track is planned to take him within range of lights which can prove useful during periods of darkness. If lights are not sighted within a reasonable time after prediction, a dangerous situation may exist, requiring resolution or action to insure safety of the vessel.

The area in which a light can be observed is normally a circle with the light as the center, and the visible range as the radius. However, on some bearings the range may be reduced by obstructions. In this case the obstructed arc might differ with height of eye and distance. Also, lights of different colors may be seen at different distances. This fact should be considered not only in predicting the distance at which a light can be seen, but also in identifying it. The condition of the atmosphere has a considerable effect upon the distance at which lights can be seen. Sometimes lights are obscured by fog, haze, dust, smoke, or precipitation which may be present at the light, or between it and the observer, but not at the observer, and possibly unknown to him. There is always the possibility of a light being extinguished. In the case of unwatched lights, this condition might not be detected and corrected at once. During periods of armed conflict, certain lights might be deliberately extinguished if they are considered of greater value to the enemy than to one's own vessels.

On a dark, clear night the visible range is limited primarily in two ways: (1) luminous intensity and (2) curvature of the earth. A weak light cannot normally be expected to be seen beyond a certain range, regardless of the height of eye. This distance is called luminous range. Light travels in almost straight lines, so that an observer below the visible horizon of the light should not expect to see the light, although the loom extending upward from the light can sometimes be seen at greater distances. Table 8 gives the distance to the horizon at various heights. The tabulated distances assume normal refraction. Abnormal conditions might extend this range somewhat (or in some cases reduce it). Hence, the geographic range, as the luminous range, is not subject to exact prediction at any given time.

The **luminous range** is the maximum distance at which a light can be seen under existing visibility conditions. This luminous range takes no account of the elevation of the light, the observer's height of eye, or the curvature of the earth. The luminous range is determined from the known nominal luminous range, called the nominal range, and the existing visibility conditions. The **nominal range** is the maximum distance at which a light can be seen in clear weather as defined by the International Visibility Code

(meteorological visibility of 10 nautical miles). The **geographic range** is the maximum distance at which the curvature of the earth permits a light to be seen from a particular height of eye *without* regard to the luminous intensity of the light. The geographic range *sometimes* printed on charts or tabulated in light lists is the maximum distance at which the curvature of the earth permits a light to be seen from a height of eye of 15 feet above the water when the elevation of the light is taken above the height datum of the largest scale chart of the locality.

The geographic range depends upon the height of both the light and the observer, as shown in figure 1206a. In this illustration a light 150 feet above the water is shown. At this height, the distance to the horizon, by table 8, is 14.0 miles. Within this range the light, *if powerful enough and atmospheric conditions permit*, is visible regardless of the height of eye of the observer (if there is no obstruction). Beyond this range, the visible range depends upon the height of eye. Thus, by table 8 an observer with height of eye of five feet can see the light on his horizon if he is 2.6 miles beyond the horizon of the light, or a total of 16.6 miles. For a height of 30 feet the distance is 14.0+6.3=20.3 miles. If the height of eye is 70 feet, the geographic range is 14.0+9.6=23.6 miles.

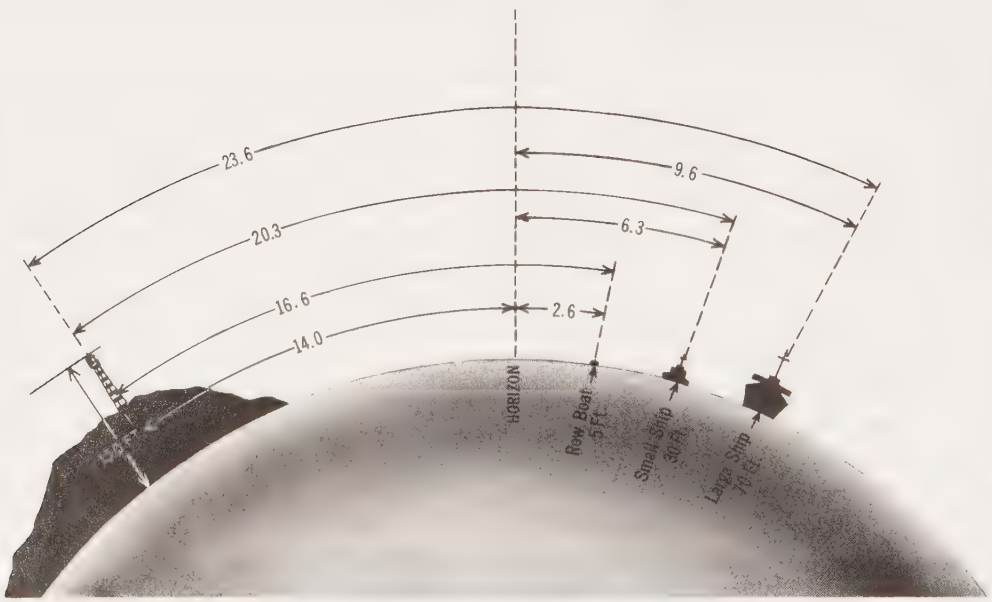

FIGURE 1206a.—Geographic range of visibility of a light.

Except for range and some directional lights, the nominal range is listed in the U.S. Coast Guard *Light List*. The **Luminous Range Diagram** shown in figure 1206b is used to convert the nominal range to the luminous range. When using this diagram, it must be remembered that the ranges obtained are approximate, the transmissivity of the atmosphere may vary between the observer and the light, and *glare from background lighting will reduce considerably the range at which lights are sighted*. After estimating the meteorological visibility with the aid of the Meteorological Optical Range Table shown in table 1206, the Luminous Range Diagram is entered with the nominal range on the horizontal nominal range scale; a vertical line is followed until it intersects the curve or reaches the region on the diagram representing the meteorological visibility; from this point or region a horizontal line is followed until it intersects the vertical luminous range scale.

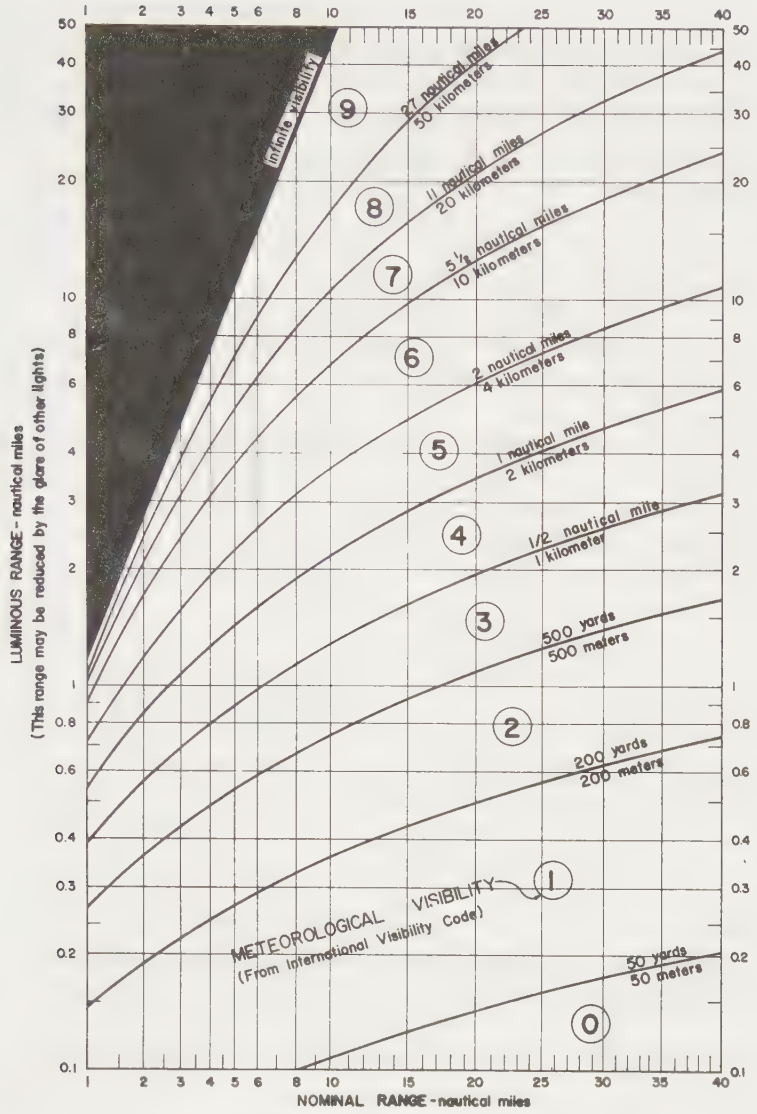

FIGURE 1206b.—Luminous Range Diagram.

Example 1.—The nominal range of a light as extracted from the *Light List* is 15 nautical miles.

Required.—The luminous range when the meteorological visibility is (1) 11 nautical miles and (2) 1 nautical mile.

Solution.—To find the luminous range when the meteorological visibility is 11 nautical miles, the Luminous Range Diagram is entered with nominal range 15 nautical miles on the horizontal nominal range scale; a vertical line is followed until it intersects the curve on the diagram representing a meteorological visibility of 11 nautical miles; from this point a horizontal line is followed until it intersects the vertical luminous range scale at 16 nautical miles. A similar procedure is followed to find the luminous range when the meteorological visibility is 1 nautical mile.

Answers.—(1) 16 nautical miles; (2) 3 nautical miles.

In predicting the range at which a light can be seen, one should first determine the geographic range to compare this range with the luminous range, if known. If the geographic range is less than the luminous range, the geographic range must be taken as the limiting range. If the luminous range is less than the geographic range, the luminous range must be taken as the limiting range.

These predictions are simple when using the U.S. Coast Guard *Light List* because only nominal ranges are tabulated. Also the current practice of the National Ocean Survey is to follow the *Light List* when printing the range of a light on a chart.

Example 2.—The nominal range of a navigational light 120 feet above the chart datum is 20 nautical miles. The meteorological visibility is 27 nautical miles.

Required.—The distance at which an observer at a height of eye of 60 feet can expect to see the light.

Solution.—The maximum range at which the light may be seen is the lesser of the luminous and geographic ranges.

At 120 feet the distance to the horizon, by table 8, is 12.5 miles. Adding 8.9 miles, the distance to the horizon at a height of eye of 60 feet, the geographic range (12.5 mi. + 8.9 mi. = 21.4 mi) is found to be less than the luminous range, which is 40 nautical miles.

Code No.	Weather	Yards
0	Dense fog	Less than 50
1	Thick fog	50–200
2	Moderate fog	200–500
3	Light fog	500–1000
		Nautical Miles
4	Thin fog	½–1
5	Haze	1–2
6	Light haze	2–5½
7	Clear	5½–11
8	Very clear	11.0–27.0
9	Exceptionally clear	Over 27.0

From the International Visibility Code

TABLE 1206.—Meteorological Optical Range Table.

Answer.—21 nautical miles. Because of various uncertainties, the range is given only to the nearest whole mile.

If the range of a light as printed on a chart, particularly a foreign chart or a reproduction of a foreign chart, or tabulated in a light list other than the U.S. Coast Guard *Light List*, approximates the geographic range for a 15-foot height of eye of the observer, one is generally safe in assuming that this range is the geographic range. With lesser certainty, one may also assume that the lesser of the geographic and nominal ranges is printed on the chart or tabulated in the light list. Using these assumptions, the predicted range is then found by adding the distance to the horizon for both the light and the observer, or approximately, by the *difference* between 4.4 miles (the distance to the horizon at a height of 15 feet) and the distance for the height of eye of the observer (a constant for any given height) and *adding* this value to the tabulated or charted geographic range (subtracting if the height of eye is less than 15 feet). In making a prediction, one should keep in mind the possibility of the luminous range being *between* the tabulated or charted geographic range and the predicted range. The intensity of the light, if known, should be of assistance in identifying this condition.

Example 3.—The range of a light as printed on a foreign chart is 17 miles. The light is 120 feet above chart datum. The meteorological visibility is 10 nautical miles.

Required.—The distance at which an observer at a height of eye of 60 feet can expect to see the light.

Solution.—At 120 feet the distance to the horizon, by table 8, is 12.5 miles. Adding 4.4 miles (the distance to the horizon at a height of 15 feet), the geographic range is found to approximate the range printed on the chart. Then assuming that the latter range is the geographic range for a 15-foot height of eye of the observer and that the nominal range is the greater value, the predicted range is found by adding the distance to the horizon for both the light and the observer (predicted range = 12.5 mi. + 8.9 mi. = 21.4 mi.). The additional distance, i.e., the distance in excess of the assumed charted geographic range, is dependent upon the luminous intensity of the light and the meteorological visibility.

If one is approaching a light, and wishes to predict the *time* at which it should be sighted, he first predicts the range. It is then good practice to draw a circle indicating the visible range. The point at which the course line crosses the circle of visible range is the predicted position of the vessel at the time of sighting the light. The predicted time of arrival at this point is the predicted time of sighting the light. The direction of the light from this point is the predicted bearing at which the light should be sighted. Conversion of the true bearing to a relative bearing is usually helpful in sighting the light. The accuracy of the predictions depends upon the accuracy of the predicted range, and the accuracy of the predicted time and place of crossing the visible range circle. If the course line crosses the visible range circle at a small angle, a small lateral error in track may result in a large error of prediction, both of bearing and time. This is particularly apparent if the vessel is *farther* from the light than predicted, in which case the light might be passed without being sighted. Thus, if a light is not sighted at the predicted time, the error *may* be on the side of safety. However, such an interpretation should not be given unless confirmed by other information, for there is always the possibility of reduced visible range, or of the light being extinguished.

When a light is first sighted, one might determine whether it is on the horizon by immediately reducing the height of eye by several feet, as by squatting or changing position to a lower height. If the light disappears, and reappears when the original height is resumed, it is on the horizon. This process is called **bobbing a light.** If a vessel has considerable vertical motion due to the condition of the sea, a light sighted on the horizon may alternately appear and disappear. This may lead the unwary to assign faulty characteristics and hence to err in its identification. The true characteristics should be observed after the distance has decreased, or by increasing the height of eye of the observer.

1207. Radar horizon.—The distance to the radar horizon is the distance between the transmitter and the point at which the radar rays graze the surface of the earth. In the standard atmosphere, radar rays, like light rays, are bent or refracted slightly downwards, approximating the curvature of the earth. The distance to the radar horizon exceeds the distance to the geometrical horizon (art. 723) by about 15 percent and the distance to the visible horizon (art. 724) by about 6 percent. Where h is the height of the radar antenna in feet, the distance, D, to the radar horizon in nautical miles, assuming standard atmospheric conditions, may be found from the formula

$$D=1.22\sqrt{h}. \tag{40}$$

Although this formula is based upon a wavelength of 3 centimeters, it may be used in the computation of the distance to the radar horizon for other wavelengths normally used with navigational or surface search radar.

Example.—The height of the antenna of the surface search radar above the water is 81 feet.

Required.—Distance to the radar horizon.

Solution.—

$$D=1.22\sqrt{h} \qquad (40)$$
$$=1.22\sqrt{81}$$
$$D=11.0 \text{ nautical miles.}$$

Problems

1204. The navigator of a vessel steaming on a steady course at 17 knots observes the following bearings from ahead as indicated:

	Time	Object	Bearing from ahead		Time	Object	Bearing from ahead
(1)	1237	*A*	42°	(3)	1325	*C*	25°
	1258	*A*	68°		1350	*C*	57°
(2)	1306	*B*	40°	(4)	1401	*D*	79°
	1321	*B*	59°		1452	*D*	103°

Required.—In each case, the distance off at the time of the second bearing, and the distance when abeam, using table 7.

Answers.—

	Object	Dist. at 2nd bearing	Dist. abeam
(1)	*A*	9.2	8.5
(2)	*B*	8.3	7.1
(3)	*C*	5.7	4.8
(4)	*D*	34.8	34.0

1205. A vessel is steaming on course 193° at 20 knots. The following true bearings are observed on the objects indicated:

	Time	Object	True Bearing		Time	Object	True Bearing
(1)	0800	*A*	229°	(4)	0912	*D*	215°.5
	0836	*A*	265°		0927	*D*	238°
(2)	0840	*B*	238°	(5)	0929	*E*	223°
	0855	*B*	283°		0954	*E*	253°
(3)	0855	*C*	256°.5	(6)	0959	*F*	233°
	0906	*C*	283°		1031	*F*	272°

Required.—Without plotting, and without the use of table 7, determine the distances off *A*, *B*, *D*, and *E* at the time of the second bearing, and the distances off *B*, *C*, *D*, *E*, and *F* when abeam.

Answers.—

	Object	Dist. at 2nd bearing	Dist. abeam
(1)	*A*	12.0	—
(2)	*B*	5.0	5.0
(3)	*C*	—	7.3
(4)	*D*	5.0	3.5
(5)	*E*	8.3	7.3
(6)	*F*	—	10.7

CHAPTER XIII

COMPASS CONVERSIONS

1301. Magnetic compass error.—Directions relative to the northerly direction along a geographic meridian are **true.** In this case, true north is the **reference direction.** If a compass card is horizontal and oriented so that a straight line from its center to 000° points to true north, any direction measured by the card is a true direction and has no error (assuming there is no calibration or observational error). If the card remains horizontal but is rotated so that it points in any other direction, the amount of the rotation is the **compass error.** Stated differently, compass error is the angular difference between true north and **compass north** (the direction north as indicated by a magnetic compass). It is named east or west to indicate the side of true north on which compass north lies.

If a magnetic compass is influenced by no other magnetic field than that of the earth, and there is no instrumental error, its magnets are aligned with the magnetic meridian at the compass, and 000° of the compass card coincides with **magnetic north.** All directions indicated by the card are **magnetic.** As stated in volume I, the angle between geographic and magnetic meridians is called **variation** (**V** or **Var.**). Therefore, if a compass is aligned with the magnetic meridian, compass error and variation are the same.

When a compass is mounted in a vessel, it is generally subjected to various magnetic influences other than that of the earth. These arise largely from induced magnetism in metal decks, bulkheads, masts, stacks, boat davits, guns, etc., and from electromagnetic fields associated with direct current in electrical circuits. Some metal in the vicinity of the compass may have acquired permanent magnetism. The actual magnetic field at the compass is the vector sum, or resultant (art. 117), of all individual fields at that point. Since the direction of this resultant field is generally not the same as that of the earth's field alone, the compass magnets do not lie in the magnetic meridian, but in a direction that makes an angle with it. This angle is called **deviation** (**D** or **Dev.**). Thus, deviation is the angular difference between magnetic north and compass north. It is expressed in angular units and named east or west to indicate the side of magnetic north on which compass north lies. Thus, deviation is the error of the compass in pointing to magnetic north, and all directions measured with compass north as the reference direction are **compass directions.** Since variation and deviation may each be either east or west, the effect of deviation may be to either increase or decrease the error due to variation alone. The algebraic sum (art. 106) of variation and deviation is the total compass error.

For computational purposes, deviation and compass error, like variation, may be designated positive (+) if east and negative (—) if west.

Variation changes with location. Deviation depends upon the magnetic latitude and also upon the individual vessel, its trim and loading, whether it is pitching or rolling, the heading (orientation of the vessel with respect to the earth's magnetic field), and the location of the compass within the vessel. Therefore, deviation is not published on charts.

1302. Deviation table.—In practice aboard ship, the deviation is reduced to a minimum through adjustment of the compass. The remaining value, called **residual deviation,** is determined on various headings and recorded in some form of **deviation table.** Figure 1302 shows the form used by the United States Navy. This table is entered with the magnetic heading, and the deviation on that heading is determined from the tabulation, separate columns being given for degaussing (DG) equipment off and on. If the deviation is not more than about 2° on any heading, satisfactory results may be obtained by entering the values at intervals of 45° only.

FIGURE 1302.—Deviation table.

If the deviation is small, no appreciable error is introduced by entering the table with either magnetic or compass heading. If the deviation on some headings is large, the desirable action is to reduce it, but if this is not practicable, a separate deviation table for compass heading entry may be useful. This may be made by applying the tabulated deviation to each entry value of magnetic heading, to find the corresponding compass heading, and then interpolating between these to find the value of deviation at each 15° compass heading.

1303. Applying variation and deviation.—As indicated in article 1301, a single direction may have any of several numerical values depending upon the reference direction used. One should keep clearly in mind the relationship between the various expressions of a direction. Thus, true and magnetic directions differ by the variation, magnetic and compass directions differ by the deviation, and true and compass directions differ by the compass error.

If variation or deviation is easterly, the compass card is rotated in a clockwise direction. This brings smaller numbers opposite the lubber's line. Conversely, if either error is westerly, the rotation is counterclockwise and larger numbers are brought opposite the lubber's line. Thus, if the heading is 090° true (fig. 1303, A) and variation is 6°E, the magnetic heading is 090°−6°=084° (fig. 1303, B). If the deviation on this heading is 2°W, the compass heading is 084°+2°=086° (fig. 1303, C). Also, compass error is 6°E−2°W=4°E, and compass heading is 090°−4°=086°. If compass error is easterly, the compass reads too low (in comparison with true directions), and if it is westerly, the reading is too high. Many rules-of-thumb have been devised as an aid to the memory, and any which assist in applying compass errors in the right direction are of value. However, one may forget the rule or its method of application, or may wish to have an independent check. If he understands the explanation given above,

he can determine the correct sign without further information. The same rules apply to the use of gyro error. Since variation and deviation are compass errors, the process of removing either from an indication of a direction (converting compass to magnetic or magnetic to true) is often called **correcting.** Conversion in the opposite direction (inserting errors) is then called **uncorrecting.**

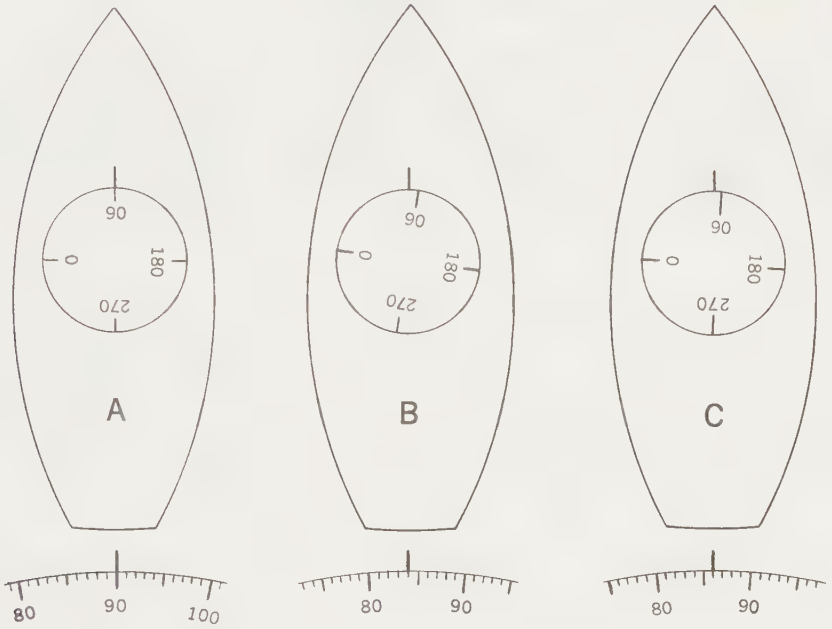

FIGURE 1303.—Effect of variation and deviation on the compass card.

Example.—A vessel is on course 215° true in an area where the variation is 7°W. The deviation is as shown in figure 1302. Degaussing is off. The gyro error (GE) is 1°E. A lighthouse bears 306°.5 by magnetic compass.

Required.—(1) Magnetic heading (MH).
(2) Deviation.
(3) Compass heading (CH).
(4) Compass error.
(5) Gyro heading.
(6) Magnetic bearing of the lighthouse.
(7) True bearing of the lighthouse.
(8) Relative bearing (art. 406) of the lighthouse.

Solution.—

	TH	215°
	V	7° W
(1)	MH	222°
(2)	D	1°.5 W
(3)	CH	223°.5

The deviation is taken from the deviation table (fig. 1302), to the nearest half degree.

(4) Compass error is 7°W+1°.5W=8°.5W.

	TH	215°
	GE	1° E
(5)	H_{pgc}	214°

	CB	306°.5
	D	1°.5 W
(6)	MB	305°
	V	7° W
(7)	TB	298°

(8) RB=TB−TH=298°−215°=083°.

Answers.—(1) MH 222°, (2) D 1°.5W, (3) CH 223°.5, (4) CE 8°.5W, (5) H_{pgc} 214°, (6) MB 305°, (7) TB 298°, (8) RB 083°.

Problems

1303a. Fill in the blanks in the following:

	TC °	*V* °	*MC* °	*D* °	*CC* °	*CE* °
(1)	105	15 E	—	5 W	—	—
(2)	—	—	—	4 E	215	14 E

(6)	009	—	357	—	—	10 E
(7)	—	2 W	—	6 E	015	—
(8)	—	—	210	—	214	1 W

Answers.—(1) MC 090°, CC 095°, CE 10°E; (2) TC 229°, V 10°E, MC 219°; (3) TC 060°, MC 072°, D 5°E; (4) V 10°W, D 6°E, CE 4°W; (5) V 6°E, CC 219°, CE 3°E; (6) V 12°E, D 2°W, CC 359°; (7) TC 019°, MC 021°, CE 4°E; (8) TC 213°, V 3°E, D 4°W.

1303b. A vessel is on course 150° by compass in an area where the variation is 19°E. The deviation is as shown in figure 1302. Degaussing is on.

Required.—(1) Deviation.

(2) Compass error.

(3) Magnetic heading.

(4) True heading.

Answers.—(1) D 1°E, (2) CE 20°E, (3) MH 151°, (4) TH 170°.

1303c. A vessel is on course 055° by gyro and 041° by magnetic compass. The gyro error is 1°W. The variation is 15°E.

Required.—The deviation on this heading.

Answer.—D 2°W.

1303d. A vessel is on course 177° by gyro. The gyro error is 0°.5E. A beacon bears 088° by magnetic compass in an area where variation is 11°W. The deviation is as shown in figure 1302, degaussing off.

Required.—The true bearing of the beacon.

Answer.—TB 076°.

CHAPTER XIV

CONVERSION ANGLE

1401. Introduction.—A bearing obtained by radio, like one determined in any other manner, provides means for establishing a line of position. By heading in the direction from which the signal is coming, one can proceed toward, or **home** on, the transmitter. In thick weather one should avoid heading directly toward the source of radiation unless he has reliable information to indicate that he is some distance away. In 1934 the Nantucket Lightship was rammed and sunk by a ship homing on its radiobeacon.

Radio waves, like light, travel along great circles. Except in high latitudes, visual bearings can usually be plotted as straight lines on a Mercator chart, without significant error. Radio bearings, however, are often observed at such positions with respect to the transmitter that the use of a rhumb line is not satisfactory. Under these conditions it is customary to apply the **conversion angle,** the difference between the rhumb line direction and the initial great-circle direction, as a correction to the observed angle, to find the equivalent rhumb line. Such a correction is not needed when a bearing is plotted on a gnomonic chart or one on which a straight line is a good approximation of a great circle. In other situations, a correction may be necessary.

If the transmitter and receiver are on the same meridian, or are both on the equator, no correction is needed because rhumb lines and great circles coincide under these conditions. The size of the correction increases with degree of departure from these conditions, and with greater distance between transmitter and receiver.

1402. Convergence of the meridians.—Due to the meridians converging at the poles, the great circle between two points, except those points on the equator or same meridian, intersects all meridians at different angles. The difference between the initial and final great-circle directions is the convergence of the meridians. Because of this convergence the initial direction and the reciprocal of the final direction do not differ by 180°. As shown in figure 1402, the initial direction of the great circle between A and B on the same side of the equator is angle A; the final direction at B is 180°−B. Therefore, in terms of the angles of the spherical triangle PnAB,

$$\text{convergence of the meridians, } c=180°-A-B$$

$$\frac{c}{2}=90°-\left(\frac{A+B}{2}\right)$$

$$\cot\frac{1}{2}c=\tan\frac{1}{2}(A+B).$$

Using Napier's Analogies (art. 143), the convergence of the meridians can be expressed in terms of difference of latitude (l) and difference of longitude (DLo).

$$\tan\frac{1}{2}(A+B)=\frac{\cos\frac{1}{2}(a-b)}{\cos\frac{1}{2}(a+b)}\cot\frac{1}{2}C=\frac{\cos\frac{1}{2}(PnB-PnA)}{\cos\frac{1}{2}(PnB+PnA)}\cot\frac{1}{2}APnB$$

$$\cot\frac{1}{2}c=\frac{\cos\frac{1}{2}l}{\sin Lm}\cot\frac{1}{2}DLo$$

$$\tan\frac{1}{2}c=\frac{\sin Lm}{\cos\frac{1}{2}l}\tan\frac{1}{2}DLo. \tag{41}$$

As shown in figure 1402, the conversion angle is equal to one-half the convergence of the meridian. For small differences of latitude, cos l can be considered 1 without introducing a significant error. Therefore, for small differences of latitude, equation 41 can be simplified:

$$\text{tan conversion angle}=\sin Lm\tan\frac{1}{2}DLo. \tag{42}$$

The tangent of a small angle equals, approximately, the angle in radians. Therefore, for small values of DLo and l (up to 15° to 20°), equation 42 can be simplified:

$$\text{conversion angle}=\frac{1}{2}DLo\sin Lm. \tag{43}$$

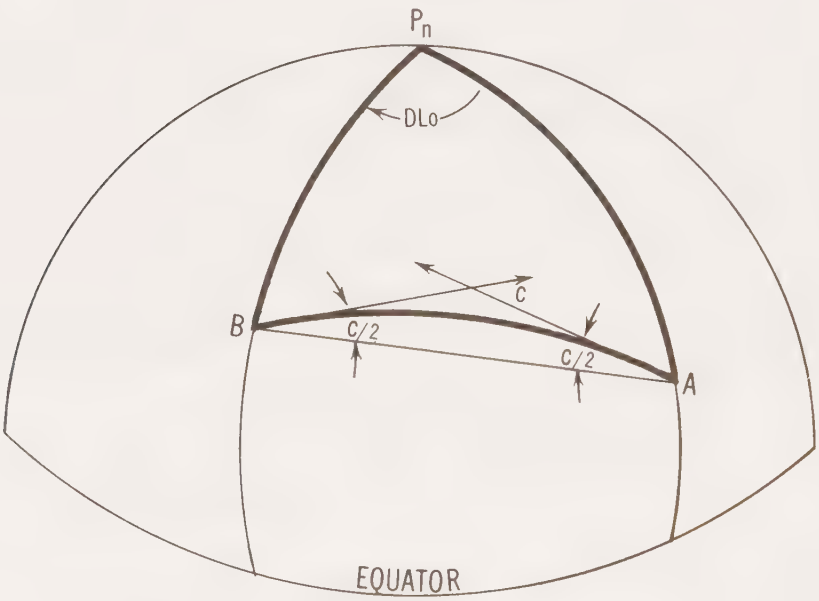

FIGURE 1402.—Convergence of the meridians and conversion angle.

1403. Conversion angles are given in table 1. This table is used to convert great circle to rhumb line directions or vice versa. If the difference of longitude is not more than 4°.5, and the mid latitude between transmitter and receiver is not more than 85°, the first part of the table should be used. The simplifying assumptions used in the computation of this part of the table do not introduce a significant error within the limits of the table.

The sign of the correction can be determined by referring to the rules given at the bottom of each page of table 1. These follow from the fact that the great circle is nearer the pole than the rhumb line. The sign can be visualized by means of a simple sketch, as shown in figure 1403.

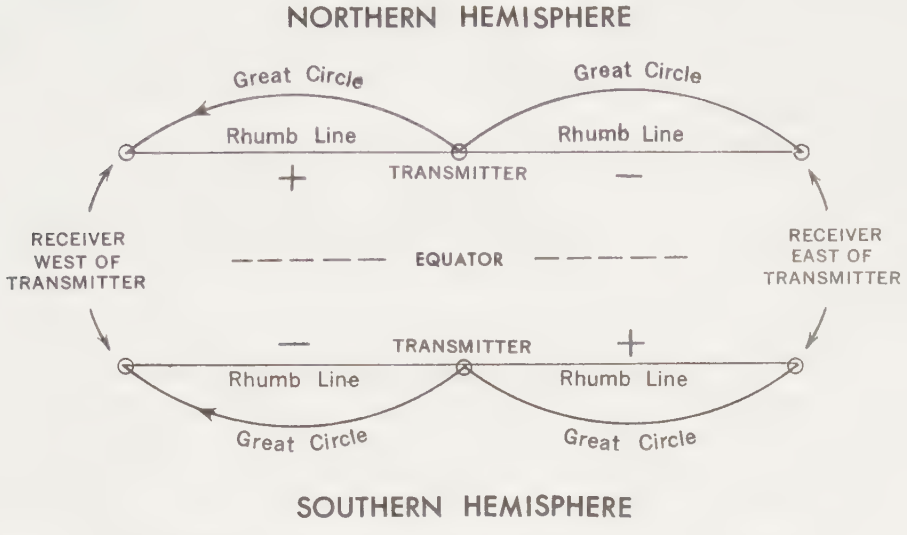

FIGURE 1403.—Sign of conversion angle correction to radio bearings.

Example 1.—The DR position of a ship is lat. 42°15′.2N, long. 9°48′.6W. A radio bearing is taken on Cabo Montedor Light Station, at lat. 41°45′00″N, long. 8°52′20″W. The reading, corrected for calibration error, is 125°.5.

Required.—The equivalent rhumb line bearing.

Solution.—

	Latitude	*Longitude*
Receiver	42°15′.2N	9°48′.6W
Transmitter	41°45′.0N	8°52′.3W
Difference	30′.2	56′.3=0°.9
Mid latitude	42°.0	
Correction	(+)0°.3 (from table 1)	
Great-circle bearing	125°.5	
Rhumb line bearing	125°.8	

Answer.—B 125°.8.

Example 2.—The DR position of a ship is lat. 34°20′.6N, long. 124°18′.6W. A radio bearing is taken on Point Loma Light Station, at 32°40′.0N, long. 117°14′.6W.

Required.—The conversion angle correction.

Solution.—Enter the second part of table 1 with the nearest tabular values of latitude of the receiver (35°), DLo (5°), and latitude of the transmitter (30°) as arguments to extract the base correction, (+)1°.3. With two of the arguments held constant, find, successively, the change in the base correction for the difference between the third argument and its corresponding actual value. With latitude of transmitter and DLo held constant, the change in the base correction for the difference between the latitude of receiver argument and the actual latitude of the receiver is 0°.0. With latitude of receiver and latitude of transmitter arguments held constant, the change in the base correction for the difference between the DLo argument and the actual DLo is (+)0°.6. With latitude of receiver and DLo arguments held constant, the change in the base

correction for the difference between the latitude of transmitter argument and the actual latitude of the transmitter is 0°.1. Therefore, the conversion angle correction is (+)2°.0 (1°.3+0°.0+0°.6+0°.1).

Answer.—Correction 2°.0.

Since radio bearings are generally somewhat less accurate than visual bearings, and often are observed at greater distances, positions obtained by them are generally considered of insufficient accuracy to be termed fixes, and so are usually considered estimated positions. However, judgment should govern the reliance to be placed upon such positional information.

Some navigators estimate or assume a probable error (usually of ±2° unless conditions suggest another value) and plot lines on each side of the bearing line to indicate the probable area within which the vessel is presumed to be located

Radio bearings furnished by a direction finder station have been corrected for known errors at the receiver, but not for conversion angle. The latter should be applied by the user.

In high latitudes it is not unusual to make use of bearings on objects a considerable distance from the vessel. Because of the rapid convergence of the meridians in these areas, such bearings are not correctly represented by straight lines on a Mercator chart. If this projection is used, the bearings should be corrected in the same manner that radio bearings are corrected (using table 1), since both can be considered great circles. Neither visual nor radio bearings are corrected when plotted on a Lambert conformal chart.

Problems

1403a. The DR position of a ship is lat. 31°22′.8N, long. 121°06′.5W. A radio bearing is taken on Point Loma Light Station, at lat. 32°40′.0N, long. 117°14′.6W.

Required.—The conversion angle correction.

Answer.—Correction (+)1°.1.

1403b. The DR position of a ship is lat. 44°08′.2S, long. 62°56′.9W. A radio bearing is taken on Isla Leones Light Station, at lat. 45°03′03″S, long. 65°36′33″W. The uncorrected reading is 039°.5 relative, the ship being on true heading 205° at the moment the bearing is observed. The calibration table indicates a correction of (−) 2° should be applied.

Required.—The equivalent true rhumb line bearing.

Answer.—B 243°.5.

APPENDIX A

ABBREVIATIONS

A, amplitude; augmentation; away (altitude intercept).
a, altitude intercept (Ho∼Hc); altitude factor (change of altitude in one minute of time from meridian transit); assumed.
a_0, first Polaris correction.
a_1, second Polaris correction.
a_2, third Polaris correction
add'l, additional.
***a*L,** assumed latitude.
AM, ante meridian (before noon).
antilog, antilogarithm.
AP, assumed position.
approx., approximate, approximately.
AU, astronomical unit.
***a*λ,** assumed longitude.
B, atmospheric pressure correction (altitude); bearing, bearing angle.
BA, difference between heading and apparent wind direction.
Brg., bearing (as distinguished from bearing angle).
B_{pgc}, bearing per gyro compass.
BT, difference between heading and true wind direction.
C, Celsius (centigrade); chronometer time; compass (direction); correction; course, course angle.
CB, compass bearing.
CC, compass course; chronometer correction.
CE, chronometer error; compass error.
CH, compass heading.
cm, centimeter, centimeters.
CMG, course made good.
Cn, course (as distinguished from course angle).
co-, the complement of (90° minus).
COA, course of advance.
COG, course over ground.
coL, colatitude.
colog, cologarithm.
corr., correction.
cos, cosine.
cot, cotangent.
cov, coversine.
C_{pgc}, course per gyro compass.
csc, cosecant.
CZn, compass azimuth.
D, deviation; dip (of horizon); distance.
d, declination (astronomical); difference.
d, declination change in one hour.
D. Lat., difference of latitude.
Dec., declination.
Dec. Inc., declination increment.
Dep., departure.
Dev., deviation.
DG, degaussing.
diff., difference.
Dist., distance.
DLo, difference of longitude (arc units).
DR, dead reckoning, dead reckoning position.
D_s, dip short of horizon.
DSD, double second difference.
dur., duration.
dλ, difference of longitude (time units).
E, east.
e, base of Naperian logarithms.
e, eccentricity.
EP, estimated position.
Eq.T, equation of time.
ETA, estimated time of arrival.
F, Fahrenheit; fast; longitude factor; phase correction (altitude).
f, latitude factor.
ft., foot, feet.
G, Greenwich, Greenwich meridian (upper branch); grid (direction).
g, acceleration due to gravity; Greenwich meridian (lower branch).
GAT, Greenwich apparent time.
GB, grid bearing.
GC, grid course.
GE, gyro error.
GH, grid heading.
GHA, Greenwich hour angle.

GMT, Greenwich mean time.
GP, geographical position.
Gr., Greenwich.
GST, Greenwich sidereal time.
GV, grid variation.
GZn, grid azimuth.
h, altitude (astronomical); height above sea level.
ha, apparent altitude.
hav, haversine.
Hc, computed altitude.
Hdg., heading.
HE, heeling error; height of eye.
Ho, observed altitude.
HP, horizontal parallax.
Hp, precomputed altitude.
H_{pgc}, heading per gyro compass.
hr., hour.
hrs., hours.
hs, sextant altitude.
ht, tabulated altitude.
HW, high water.
I, instrument correction.
IC, index correction.
in., inch, inches.
int., interval.
J, irradiation correction (altitude).
K, Kelvin (temperature).
km, kilometer, kilometers.
kn., knot, knots.
L, latitude; lower limb correction for moon (from *Nautical Almanac*).
***l*,** difference of latitude; logarithm, logarithmic.
LAN, local apparent noon.
LAT, local apparent time.
lat., latitude.
LHA, local hour angle.
LL, lower limb.
Lm, middle latitude; mean latitude.
LMT, local mean time.
log, logarithm, logarithmic.
$\log_e$, natural logarithm (to the base e).
$\log_{10}$, common logarithm (to the base 10).
long., longitude.
LOP, line of position.
LST, local sidereal time.
LW, low water.
M, celestial body; meridian (upper branch); magnetic (direction); meridional parts; nautical mile, miles.
m, meridian (lower branch); meridional difference ($M_1 \sim M_2$); meter, meters; statute mile, miles.
mag., magnetic; magnitude.
MB, magnetic bearing.
mb, millibar, millibars.
MC, magnetic course.
Mer. Pass., meridian passage.
MH, magnetic heading.
mi., mile, miles.
mid, middle.
min., minute, minutes.
mm, millimeter.
mo., month.
mos., months.
mph, miles (statute) per hour.
MPP, most probable position.
MSL, mean sea level.
MZn, magnetic azimuth.
N, north.
***n*,** natural (trigonometric function).
Na, nadir.
P, atmospheric pressure; parallax; planet; pole.
p, departure, polar distance.
PC, personal correction.
pgc, per gyro compass.
P in A, parallax in altitude.
PM, post meridian (after noon).
Pn, north pole; north celestial pole.
PPI, plan position indicator.
Ps, south pole; south celestial pole.
psc, per standard compass.
p stg c, per steering compass.
Pub., publication.
PV, prime vertical.
***Q*,** Polaris correction (*Air Almanac*).
QQ′, celestial equator.
R, Rankine (temperature); refraction.
RA, right ascension.
rad, radian, radians.
RB, relative bearing.
R Bn, radiobeacon.
RDF, radio direction finder.
rev., reversed.

R Fix, running fix.
RZn, relative azimuth.
S, sea-air temperature difference correction (altitude); slow; south.
S_A, speed of apparent wind in units of ship's speed.
SD, semidiameter.
sec, secant.
sec., second, seconds.
semidur., semiduration.
SH, ship's head (heading).
SHA, sidereal hour angle.
sin, sine.
SMG, speed made good.
SOA, speed of advance.
SOG, speed over ground.
S_T, speed of true wind in units of ship's speed.
St M, statute mile, miles.
T, air temperature correction (altitude); table; temperature; time; toward (altitude intercept); true (direction).
t, dry-bulb temperature; elapsed time; meridian angle.
t′, wet-bulb temperature.
tab., table.
tan, tangent.
TB, true bearing; air temperature-atmospheric pressure correction (altitude).
TC, true course.
TH, true heading.
TR, track.
Tr., transit.
TZn, true azimuth.
U, upper limb correction for moon (from *Nautical Almanac*).
UL, upper limb.
UT, universal time.
V, variation; vertex.
***v*,** excess of GHA change from adopted value for one hour.
Var., variation.
ver, versine.
W, west.
WE, watch error.
WT, watch time.
X, parallactic angle.
yd., yard.
yds., yards.
yr., year.
yrs., years.
Z, azimuth angle; zenith.
z, zenith distance.
ZD, zone description.
Z Diff., azimuth angle difference.
Zn, azimuth (as distinguished from azimuth angle).
Zn_{pgc}, azimuth per gyro compass.
ZT, zone time.
Δ, a small increment, or the change in one quantity corresponding to unit change in another.
λ, longitude; wave length (radiant energy).
σ, standard deviation.
μ, index of refraction.
μs, microsecond.
π, ratio of circumference of circle to diameter$=3.14159+$.

SYMBOLS

Positions

- ⌓ Dead reckoning position.
- ⊙ Fix.
- ⊡ Estimated position.
- ⚠ Symbol used for one set of fixes when simultaneously fixing by two means, e.g., visual and radar; sometimes used for radionavigation fixes.

Mathematical Symbols

- \+ Plus (addition)
- − Minus (subtraction)
- ± Plus or minus
- ~ Absolute difference
- × Times (multiplication)
- ÷ Divided by (division)
- $\sqrt{\ }$ Square root
- ∠ Angle
- ∴ Therefore
- $\sqrt[n]{\ }$ nth root
- = Equals
- ≠ Not equal to
- ≈ Nearly equal to
- > Is greater than
- < Is less than
- ∫ Integral sign
- ∞ Infinity
- . . . Repeating decimal

Celestial Bodies

- ☉ Sun
- ☾ Moon
- ☿ Mercury
- ♀ Venus
- ⊕ Earth
- ♂ Mars
- ♃ Jupiter
- ♄ Saturn
- ♅ Uranus
- ♆ Neptune
- ♇ Pluto
- ☆ Star
- ☆-P Star-planet altitude correction (altitude)
- ☉ ☾ Lower limb
- ⊖ ☾ Center
- ☉ ☾ Upper limb
- ● New moon
- ● Crescent moon
- ◐ First quarter
- ○ Gibbous moon
- ○ Full moon
- ○ Gibbous moon
- ◑ Last quarter
- ● Crescent moon

Signs of the Zodiac

- ♈ Aries (vernal equinox)
- ♉ Taurus
- ♊ Gemini
- ♋ Cancer (summer solstice)
- ♌ Leo
- ♍ Virgo
- ♎ Libra (autumnal equinox)
- ♏ Scorpius
- ♐ Sagittarius
- ♑ Capricornus (winter solstice)
- ♒ Aquarius
- ♓ Pisces

Miscellaneous Symbols

^{y} Years	✳ Interpolation impractical
^{m} Months	° Degrees
^{d} Days	′ Minutes of arc
^{h} Hours	″ Seconds of arc
^{m} Minutes of time	☌ Conjunction
^{s} Seconds of time	☍ Opposition
▬ Remains below horizon	□ Quadrature
▭ Remains above horizon	☊ Ascending node
//// Twilight all night	☋ Descending node

APPENDIX D

MISCELLANEOUS DATA

Exact relationships shown by asterisk (*). See footnote on page 649.

Area

1 square inch = 6.4516 square centimeters*

1 square foot = 144 square inches*
= 0.09290304 square meter*
= 0.000022957 acre

1 square yard = 9 square feet*
= 0.83612736 square meter

1 square (statute) mile = 27,878,400 square feet*
= 640 acres*
= 2.589988110336 square kilometers*

1 square centimeter = 0.1550003 square inch
= 0.00107639 square foot

1 square meter = 10.76391 square feet
= 1.195990 square yards

1 square kilometer = 247.1053815 acres
= 0.38610216 square statute mile
= 0.29155335 square nautical mile

Astronomy

Additional corrections for temperature and pressure are given on the following page.
For bubble sextant observations ignore dip and use the star corrections for Sun, planets, and stars.

The graph is entered with arguments temperature and pressure to find a zone letter; using as arguments this zone letter and apparent altitude (sextant altitude corrected for dip), a correction is taken from the table. This correction is to be applied to the sextant altitude in addition to the corrections for standard conditions (for the Sun, planets and stars from the inside front cover and for the Moon from the inside back cover).

Latitude = Apparent altitude (corrected for refraction) $-$ 1° $+ a_0 + a_1 + a_2$

The table is entered with L.H.A. Aries to determine the column to be used; each column refers to a range of 10°. a_0 is taken, with mental interpolation, from the upper table with the units of L.H.A. Aries in degrees as argument; a_1, a_2 are taken, without interpolation, from the second and third tables with arguments latitude and month respectively. a_0, a_1, a_2 are always positive. The final table gives the azimuth of *Polaris*.

The above table is for converting expressions in arc to their equivalent in time ; its main use in this Almanac is for the conversion of longitude for application to L.M.T. (*added* if *west*, *subtracted* if *east*) to give G.M.T. or vice versa, particularly in the case of sunrise, sunset, etc.

Table I is for interpolating the L.M.T. of sunrise, twilight, moonrise, etc. for latitude. It is to be noted that the interpolation is not linear, so that when using this table it is essential to take out the required phenomenon for the latitude *less* than the true latitude. The table is entered with the nearest value of the difference between the times for the tabular latitude and the next higher one, and, in the appropriate column, with the difference between true latitude and tabular latitude; the correction so obtained is applied to the time for the tabular latitude; the sign of the correction can be seen by inspection.

TABLE II—FOR LONGITUDE

Long. East or West	Difference between the times for given date and preceding date (for east longitude) or for given date and following date (for west longitude)																	
	10m	20m	30m	40m	50m	60m	1h + 10m	1h + 20m	1h + 30m	1h + 40m	1h + 50m	1h + 60m	2h 10m	2h 20m	2h 30m	2h 40m	2h 50m	3h 00m

Table II is for interpolating the L.M.T. of moonrise, moonset and the Moon's meridian passage for longitude. It is entered with longitude and with the difference between the times for the given date and for the preceding date (in east longitudes) or following date (in west longitudes). The correction is normally *added* for west longitudes and *subtracted* for east longitudes, but if, as occasionally happens, the times become earlier each day instead of later, the signs of the corrections must be reversed.

MOON CORRECTION TABLE

The correction is in two parts; the first correction is taken from the upper part of the table with argument apparent altitude, and the second from the lower part, with argument H.P., in the same column as that from which the first correction was taken. Separate corrections are given in the lower part for lower (L) and upper (U) limbs. All corrections are to be **added** to apparent altitude, *but 30′ is to be subtracted from the altitude of the upper limb.*

For corrections for pressure and temperature see page A4.

For bubble sextant observations ignore dip, take the mean of upper and lower limb corrections and subtract 15′ from the altitude.

App. Alt. = Apparent altitude = Sextant altitude corrected for index error and dip.

60 000	5·5	4·7	7·7	6·9

An alternative method to those given on pages A12–A14 is to use the graphs to give the corrections to the tabulated times of sunrise and sunset at ground level; in this case it is adequate to use the graphs for the *nearest* tabular latitude and declination. The difference in hour angle is found between the hour angle for zero depression and the hour angle at the tabular depression minus 0°·8. The difference in hour angle so found is then applied to the time of sunrise or sunset. The result will be less than 5^m in error if the declination curve cuts all the depression lines.

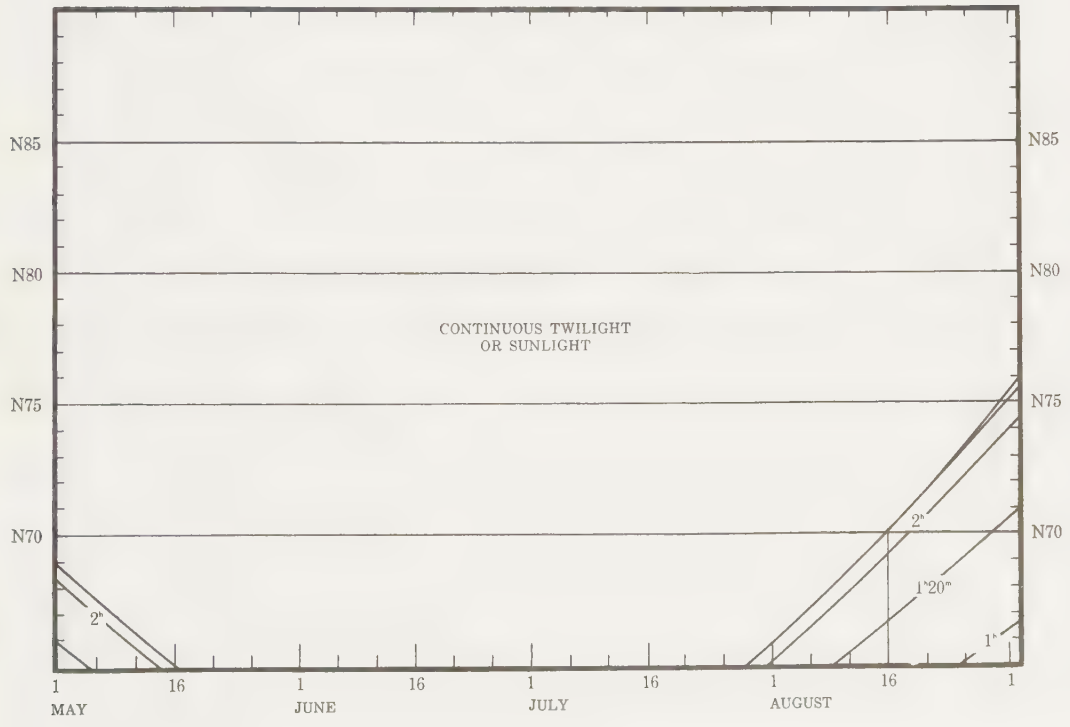

Example. To find the times of sunrise and sunset on 1975 August 23 in latitude N. 65° 17′, longitude W. 35° 15′, at a height of 37 000 feet. From Table 1, Dec.= N. 11°·6; Table 2, Depression diff. from 0°·8=3°·7.

The above table is for converting expressions in arc to their equivalent in time; its main use in this Almanac is for the conversion of longitude for application to L.M.T. (*added* if *west*, *subtracted* if *east*) to give G.M.T., or vice versa, particularly in the case of sunrise, sunset, etc.

INTERPOLATION OF G.H.A. SUN

Q, which does *not* include refraction, is to be applied to the corrected sextant altitude of *Polaris*.
Polaris: Mag. 2·1, S.H.A. 327° 53′, Dec. N. 89° 09′·2

STANDARD DOME REFRACTION

To be *subtracted* from sextant altitude when using sextant suspension in a perspex dome

60	54	60	66	72

f	0	5	10	15	20	25	30	35	40	45	50	55	f
	Temperature in °C												
0·9	+47	+36	+27	+18	+10	+ 3	− 5	−13					0·9
1·0	+26	+16	+ 6	− 4	−13	−22	−31	−40					1·0
1·1	+ 5	− 5	−15	−25	−36	−46	−57	−68					1·1
1·2	−16	−25	−36	−46	−58	−71	−83	·95					1·2
	−37	−45	−56	−67	−81	−95							

For these heights no temperature correction is necessary: take $f = 1{\cdot}0$ and use $R = R_o$

f	0·9	1·0	1·1	1·2
	When R_o is less than 10′ or the height is greater than 35,000 ft. take $f = 1{\cdot}0$ and use $R = R_o$			

Choose the column appropriate to height, in units of 1,000 ft., and find the range of altitude in which the sextant altitude lies; the corresponding value of R_o is the refraction, to be subtracted from sextant altitude, unless conditions are extreme. In that case find f from the lower table, with critical argument temperature. Use the table on the right to form the refraction, $R = R_o \times f$.

CORIOLIS (Z) CORRECTION

To be applied by moving the position line a distance Z to starboard (right) of the track in northern latitudes and to port (left) in southern latitudes. The argument is given as T.A.S. (True Air Speed) in A.P. 3270.

APPENDIX H

LONG-TERM ALMANAC

This appendix is intended for use when a more complete almanac is not available. It is based principally upon the fact that approximately correct values for the Greenwich hour angle and declination of the sun, and the Greenwich hour angle of Aries, can be obtained from an almanac that is exactly four years out of date. The differences in these values at intervals of exactly four years can be largely removed by applying an average correction to the values obtained from the tables of this appendix. The maximum error in an altitude computed by means of this appendix should not exceed 2′.0 for the sun or 1′.3 for stars.

This four-year, or quadrennial, correction varies throughout the year for the GHA of the sun (between about plus and minus one-half of a minute) and for the declination of the sun (between about plus and minus three-fourths of a minute). For the GHA of Aries the quadrennial correction is a constant, (+)1′.84. The appropriate quadrennial correction is applied once for each full four years which has passed since the base year of the tabulation (1972 in this appendix).

The tabulated values for GHA−175° and declination of the sun and GHA of Aries are given in four columns, labeled 0, 1, 2, and 3. The "0" column contains the data for the leap year in each four-year cycle and the 1, 2, and 3 columns contain data for, respectively, the first, second, and third years following each leap year.

The GHA−175° and declination of the sun are given at intervals of three days throughout the four-year cycle, except for the final days of each month, when the interval varies between one and four days. Linear interpolation is made between entries to obtain data for a given day. Additional corrections to the GHA of the sun of 15° per hour, 15′ per minute, and 15″ per second are made to obtain the GHA at a given time. Declination of the sun is obtained to sufficient accuracy by linear interpolation alone.

The GHA of Aries is given for each month of the four-year cycle. Additional corrections of 0°59′.14 per day, 15°02′.5 per hour, 15′ per minute, and 15″ per second are made to obtain the GHA at a given time.

The SHA and declination of 38 navigational stars are given for the base year, 1972.0. Annual (not quadrennial) corrections are made to these data to obtain the values for a given year and tenth of a year.

A multiplication table is included as an aid in applying corrections to tabulated values.

Sun tables. 1. Subtract 1972 from the year and divide the difference by four, obtaining (*a*) a whole number, and (*b*) a remainder. Enter column indicated by remainder (*b*) and take out values on either side of given time and date.

2. Multiply quadrennial correction for each value by whole number (*a*) obtained in step 1 and apply to tabulated values plus 175°.

3. Divide difference between corrected values by number of days (usually three) between them to determine daily change.

4. Multiply daily change by number of days and tenths since 0^h GMT of earlier tabulated date, and mark correction plus (+) or minus (−) as appropriate.

5. (GHA only.) Enter multiplication table with hours, minutes, and seconds of GMT, and take out corrections *A*, *B*, and *C*, respectively. These are all positive.

6. Apply corrections of steps 4 and 5 to corrected *earlier* values of step 2.

Example.—Find GHA and declination of sun at GMT $17^h13^m49^s$ on July 18, 2002.

Solution.—*Steps* 1 *and* 2: (2002−1972)÷4=7, remainder 2. Use column 2, and multiply quadrennial corrections by 7. Corrected values: GHA, July 16, 178°31′.1+(7×0′.05)=178°31′.5; July 19, 178°27′.2+(7×0′.06)=178°27′.6. Dec., July 16, 21°27′.9N−(7×0′.41)=21°25′.0N; July 19, 20°57′.5N−(7×0′.44)=20°54′.4N.

corr.	(−)27′.5	
0^h July 16	21°25′.0 N	*Step 6*
Dec.	20°57′.5 N	

Aries table. 1. Subtract 1972 from the year and divide the difference by four, obtaining (*a*) a whole number, and (*b*) a remainder. Enter column indicated by remainder (*b*) and take out value for given month.

2. Enter multiplication table with whole number (*a*) of step 1, day of month, hours of GMT, minutes of GMT, and seconds of GMT, and take out corrections *D*, *E*, *F*, *G*, and *C*, respectively.

3. Add values of steps 1 and 2.

Example.—Find GHA♈ at GMT $11^h06^m33^s$ on November 28, 1995.

Solution.—*Step* 1: (1995−1972)÷4=5, remainder 3. Use column 3.

	GHA♈

Stars table. 1. Enter table with star name, and take out tabulated values.

2. Subtract 1972.0 from given year and tenth, and multiply annual correction by difference. Apply as correction (+or−, as appropriate) to value of step 1.

Example.—Find SHA and declination of Spica on September 11, 2011.

Solution.—From decimal table, September 11, 2011=2011.7. 2011.7−1972.0=39.7.

SHA			*Declination*		
1972.0	159°04′.3	*Step 1*	1972.0	11°01′.0 S	*Step 1*
39.7×(−)0′.79	(−)31′.4	*Step 2*	39.7×0.31	(+)12′.3	*Step 2*
SHA	158°32′.9		Dec.	11°13′.3 S	

To determine GHA of star, add GHA ♈ and SHA ✡ for given time and date.

In **North latitude**, when the body is rising or East of the meridian, the tabulated azimuths are reckoned from North to East; and when the body is setting or West of the meridian, the tabulated azimuths are reckoned from North to West.

In **South latitude**, when the body is rising or East of the meridian, the tabulated azimuths are reckoned from South to East; and when the body is setting or West of the meridian, the tabulated azimuths are reckoned from South to West.

In **North latitude**, when the star is rising or East of the meridian, the tabulated azimuths are reckoned from North to East; **and** when the star is setting or West of the meridian, the tabulated azimuths are reckoned from North to West.

In **South latitude**, when the star is rising or East of the meridian, the tabulated azimuths are reckoned from South to East; **and** when the star is setting or West of the meridian, the tabulated azimuths are reckoned from South to West.

When the **latitude** and **declination** are of **different name**, the tables are to be entered with the **supplement** of the hour angle and the **supplement** of the tabulated azimuth is to be taken for the required true bearing.

AZIMUTH OR TRUE BEARING.

In **North latitude**, when the star is rising or East of the meridian, the tabulated azimuths are reckoned from North to East; and when the star is setting or West of the meridian, the tabulated azimuths are reckoned from North to West.

In **South latitude**, when the star is rising or East of the meridian, the tabulated azimuths are reckoned from South to East; and when the star is setting or West of the meridian, the tabulated azimuths are reckoned from South to West.

When the **latitude** and **declination** are of **different name**, the tables are to be entered with the supplement of the hour angle and the supplement of the tabulated azimuth is to be taken for the required true bearing.

DECLINATION SAME NAME AS LATITUDE

Obtain from the predictions the high water and low water, one of which is before and the other after the time for which the height is required. The difference between the times of occurrence of these tides is the duration of rise or fall, and the difference between their heights is the range of tide for the above table. Find the difference between the nearest high or low water and the time for which the height is required.

Enter the table with the duration of rise or fall, printed in heavy-faced type, which most nearly agrees with the actual value, and on that horizontal line find the time from the nearest high or low water which agrees most nearly with the corresponding actual difference. The correction sought is in the column directly below, on the line with the range of tide.

When the nearest tide is high water, subtract the correction.

When the nearest tide is low water, add the correction.

[1]Current is rotary, turning clockwise. Minimum current of 0.9 knot sets SW. about time of "Slack, flood begins" at The Narrows. Minimum current of 0.5 knot sets NE. about 1 hour before "Slack, ebb begins" at The Narrows.

[2]Maximum flood, -0h 50m; maximum ebb, +0h 55m.

[3]Flood begins, -2h 15m; maximum flood, -0h 05m; ebb begins, +0h 05m; maximum ebb, -1h 50m.

[4]The values for the Hudson River are for the summer months, when the fresh-water discharge is a minimum.

TABLE 3.—VELOCITY OF CURRENT AT ANY TIME

Use Table A for all places except those listed below for Table B.
Use Table B for Cape Cod Canal, Hell Gate, Chesapeake and Delaware Canal and all stations in Table 2 which are referred to them.

1. From predictions find the time of slack water and the time and velocity of maximum current (flood or ebb), one of which is immediately before and the other after the time for which the velocity is desired.
2. Find the interval of time between the above slack and maximum current, and enter the top of Table A or B with the interval which most nearly agrees with this value.
3. Find the interval of time between the above slack and the time desired, and enter the side of Table A or B with the interval which most nearly agrees with this value.
4. Find, in the table, the factor corresponding to the above two intervals and multiply the maximum velocity by this factor. The result will be the approximate velocity at the time desired.

Abbreviations 633–635
Abscissa, coordinate, described 401
Absolute accuracy, of number, defined 376
Absolute precision, of number, defined 376
Absolute value, of number, defined 375
Acceleration error, sextant altitude correction, discussed 552
Accuracy, navigational, defined 430
Acute angle, defined 390
Acute triangle, defined 392
Addition, arithmetic and algebraic, defined 378
of mathematical expressions, discussed 387
of numbers, explained 377–378
Addition and subtraction logarithms, defined 385
Adjacent angles, defined 391
Ageton Method, sight reduction, table 35 333–369
explanation of table 35 15–16
Air Almanac, extracts from 668–686
sextant altitude corrections by 556
Air temperature, altitude correction for, discussed 545
table 23 156
explanation of table 23 11
Algebra, defined 386
definitions of 386–387
principles of 386–389
Almucantar, defined 461
Altitude, angular distance, defined 461
of cone, defined 397
of cylinder, defined 396
of prism, defined 395
of pyramid, defined 395
of triangle, defined 392
Altitude change, near meridian transit, table 30 184–187
explanation of table 30 13–14
Altitude difference, sight reduction, defined 567
Altitude factor, defined 535
table 29 174–183
explanation of table 29 13
Altitude intercept, sight reduction, defined 567
Altitudes of moon, correcting 557
Altitudes of planets, correcting 558
Altitudes of stars, correcting 558
Altitudes of sun correcting 556–557
Amplitude(s), of celestial body, correction as observed on visible horizon, table 28 173
explanation of table 28 13
table 27 169–172
explanation of table 27 12–13
Angle(s), defined and discussed 390–391
Angle of incidence, described 543
Angle of refraction, described 543
Angular length, of circle, defined 401
Angular measure, discussed 401
Antilogarithm, finding of, defined 383
Apex, of cone, defined 396
of pyramid, defined 395

Page

Apparent (rectified) altitude, determination of 554
Apparent horizon, defined 459
Apparent motion of celestial bodies, defined and discussed 455–457
Apparent solar time, defined 467
Apparent sun, reference for apparent time 478
Apparent time, discussed 478–479
Arc, major and minor, of circle, defined 394
of circle, defined 394
Argument, of table 419
Arithmetic, defined 375
definitions of 375
principles of 375–386
Artificial-horizon corrections, discussed 554
Artificial-horizon sextant corrections, discussed 554
Assumed latitude, selection of 566
Assumed longitude, selection of 566–567
Assumed position, in navigational triangle 465
selection of, discussed 566–567
Astronomical day, defined 468
Astronomical refraction, defined 543
Astronomical triangle, defined 465
Asymptotes, of hyperbola, described 399
Atmospheric pressure, altitude correction for, table 24 157
explanation of table 24 11
Atmospheric pressure correction, sextant altitude, discussed 545–546
Atmospheric refraction, defined 543
Augmentation, sextant altitude correction, defined and discussed 547–548
Autumnal equinox, defined 457
Away, sight reduction, defined 567
Axes, of coordinate system, defined and described 401
Axis, major and minor, of ellipse 397
of cone, defined 397
of cylinder, defined 396
of hyperbola, described 398
of parabola, described 398
of prism, defined 395
of pyramid, defined 395
semimajor and semiminor, of ellipse 397
Axis of rotation, earth, defined 443
Azimuth, defined and discussed 461
Azimuth angle, defined and discussed 461

Back sights, altitude measurement, defined and discussed 562–563
Barometer, correction for gravity, table 12 138
explanation of table 12 7
correction for height above sea level, table 11 138
explanation of table 11 6–7
correction for temperature, table 13 139
explanation of table 13 7
Base(s), of cone, defined 396
of cylinder, defined 396
of parallelogram, defined 393
of pyramid, defined 395
of trapezoid, defined 393

	Page
Bearing, defined	447
Bearing angle, defined	447
Bias, defined	439
Biquadrantal spherical triangle, definition and solution of	411–412
Bobbing a light, defined	621
Bow and beam bearings, defined	616
Bowditch, Nathaniel; biography of	iii–vi
Braces, use of in algebra	387
Brackets, use of in algebra	387
Briggs' logarithms, defined	384
Calculus, defined	414
definitions of	414–415
principles of	414–418
Cartesian coordinates, defined	401
Celestial equator, defined	453
Celestial equator system of coordinates, discussed	458–459
Celestial horizon, defined	460
Celestial meridian, defined	453
Celestial poles, defined	453
Celestial sphere, defined and discussed	453–455
Celestial triangle, defined	464
Center, of circle, defined	394
of sphere, defined	399
Centesimal degree(s) (grades), unit of arc	401
Centesimal minute(s), unit of arc	401
Centesimal second(s), unit of arc	401
Centesimal system, angular length, defined	401
Central angle, of circle, defined	394
Centroid, of triangle, defined	392
Characteristic, of logarithm, defined	382
Chart scales, natural and numerical, table 37	371
explanation of table 37	16
Chord, of circle, defined	394
Chronometer error, defined	474
Chronometer rate, defined	474
Chronometer time, defined and discussed	474–475
Circle(s), as conic section	397
defined and discussed	394–395
of earth, discussed	443–444
Circular cone, defined	397
Circular cylinder, defined	396
Circular slide rule, discussed	385
Circumference of circle, defined	394
Circumscribed circle, of triangle, defined	392
Coaltitude, described	465
Codeclination, described	465
Colatitude, described	465
Cologarithm(s), defined and discussed	384
Common logarithm, base of	381, 384
Common tangent, defined	395
Compass course, defined	447
Compass directions, defined	623
Compass error, amplitudes, defined and discussed	514–516
azimuth by tables	510–514
defined	623
solving for	510–518
time on prime meridian, finding of	516–518
Compass north, defined	623
Compass points, conversion to degrees, table 2	23
explanation of table 2	4
Complement, of angle, defined	390
Complementary angles, defined	390
Composite sailing, defined	571
discussed	590–591
Computed altitude, defined	567
Computed and observed altitudes, comparison of	567–568
Concentric circles, defined	394
Cone(s), defined and discussed	396–397
Congruent triangles, defined	392
Conic sections, discussed	397–399
Constant, defined	414
Constant error, defined	431
Constant of the cone, defined	449
Convergence of the meridians, discussed	627–628
Convergency, discussed	449
Conversion angle, defined	627
introduction	627
table 1, discussed	628–630
table 1	18–22
explanation of table 1	3
Coordinate(s), defined and discussed	400–401
on earth, defined	444
Coordinate systems, of celestial sphere, discussed	457
Coriolis force, discussed	551–552
Correcting, compass conversions, defined	625
Cosecant formulas, defined	502
Course, defined	447
Course angle, described	447
Course line, defined	447
Course made good, defined	447
Course of advance, defined	447
Course over ground, defined	447
Critical table, interpolation, discussed	419
Cube, defined	395
Cube root, of number, defined	381
Current diagrams, discussed	607–608
Cylinder(s), defined and discussed	396
Daily rate, of chronometer, defined	474
Date line, defined and discussed	471–472
Day, defined	467
Daylight saving time, defined	467, 473–474
December solstice, defined	457
Declination, defined	454, 458
Definite integral, described	417
Deflection of the vertical, sextant altitude correction, discussed	552
Degree(s), unit of arc	401
Denominator, defined	375
Departure, defined	445
Dependent variable, described	414–415
Depressed pole, defined	460
Derivative, described	415
Deviation, defined	623
Deviation table, discussed	624
Dew point, temperature of, table 17	144–145
explanation of table 17	9
Diagonal, of polygon, defined	393
Diagram on the plane of the celestial meridian, discussed	462–464
Diameter, of circle, defined	394
of sphere, defined	399
Difference, of numbers, defined	379
Difference of latitude, discussed	445
Difference of longitude, discussed	445
Differential, described	417
Differential equation(s), defined and discussed	417–418
Differentiation, defined and discussed	415–416
Digit, defined	375
Dihedral angle, defined	391

Page

Dip, of geometrical horizon, solution 518–519
of visible horizon, solution 521
sextant altitude correction, discussed 540–542
short of the horizon, solution 521–523
table 22 154–155
explanation of table 22 10
Dip and distance of the horizon, solving for 518–523
Direction on the earth, discussed 446–448
Directrix, of parabola, described 398
Distance, measurement of, by two bearings, discussed 615
table 7 126–131
explanation of table 7 5
by vertical angle, discussed 614–615
table 9 133–135
explanation of table 9 6
of geometrical horizon, solution 519
of horizon, table 8 132
explanation of table 8 5
of visible horizon, solution 519–520
on earth, defined and discussed 445–446
speed, and time, discussed 611–613
Distance calculations, introduction 611
special cases of 616
Distance vectors, described 386
Diurnal circle, defined 454
Divided astronomical triangle, Ageton Method of solution 508–510
development of formulas 505–508
solutions of 505–510
Dividend, defined 380
Division, by logarithms, explained 383–384
of mathematical expressions, discussed 387–388
of numbers, explained 380–381
Divisor, defined 380
Double interpolation, defined 419
discussed 422–423
Double second difference, nonlinear interpolation, discussed 425
Doubling the angle on the bow, defined 616

Earth, described 443
Eccentricity, of ellipse, described 397
of hyperbola, described 398
of parabola, defined 398
Ecliptic, defined 456
Element(s), of cone, defined 396
of cylinder, defined 396
Elevated pole, defined 460
Ellipse, defined 397
Ephemeris Time, defined 479
Equal triangles, defined 392
Equation, defined 387
Equation of time, defined and discussed 478–479
Equator, defined 443
Equatorial horizontal parallax, defined 549
Equiangular polygon, defined 393
Equiangular triangle, defined 391
Equilateral polygon, defined 393
Equilateral triangle, defined 391
Equinoctial, defined 453
Equinoxes, defined 456
Error, navigational, defined and discussed 429–430
Ex-meridian altitude, discussed 535
Ex-meridian observation, defined 535
Explement, of angle, defined 391
Explementary angles, defined 391
Exponent, use of in multiplication 380
use of when expressing numbers 375

Page

Exterior angle of triangle, defined 392
Extracting a root, defined 381
Extrapolation, defined 419
discussed 427

Face(s), of polyhedron, defined 395
of pyramid, defined 395
Factoring, of mathematical expressions, defined 387
Fictitious rhumb line, on polar grid, defined 449
Finite number, defined 375
First difference, nonlinear interpolation, discussed 424–425
First estimate, meridian transit, discussed 536
First point of Aries, defined 456
use of in locating an hour circle 454
Five parts formulas, defined 497
Focal point(s) (foci or focus), of ellipse, described 397
of hyperbola, described 398
of parabola, described 397–398
Fractions, rules for handling 388–389
Frost smoke, described 550
Frustum, of cone, defined 397
Function, of a variable, defined 414
Fundamental trigonometric identities, defined 407

Geocentric parallax, defined 549
Geodesic, defined 443
Geographic range, defined 618
Geographical mile, defined 446
Geographical position, defined 465, 584
Geoidal horizon, defined 460
Geometrical horizon, described 460
Geometry, defined 389
definitions of 389–390
principles of 389–401
GHA and declination, finding of 487–492
moon 489–490
planet 490–491
star 491–492
sun 488–489
use of almanacs 487–488
Great circle(s), discussed 582–583
of sphere, defined 399, 443
Great-circle distance, defined 446
Great-circle sailing, by computation 583–590
by table 35, discussed 591–596
defined 571
discussed 583
Great-circle track, defined 447, 583
Greek alphabet 636
Greenwich apparent time, defined 478
Greenwich hour angle, defined 455, 459, 481
Greenwich mean time, defined 472
Greenwich sidereal time, defined 480
Greenwich time, defined 467
Grid course, defined 447
Grid direction, defined and discussed 448–450
Grid variation, defined 449
Grivation, defined 449

Haversines, table 34 297–332
explanation of table 34 15
Heading, defined 447
Height of eye correction, defined 541
Height of tide, finding of for any time 602–604
Heliocentric parallax, defined 549
Hexagon, defined 393

	Page
High water, defined	599
High water full and change, tidal information	600
Home, on radio bearings	627
Horizon(s), discussed	459–460
system of coordinates, discussed	460–461
Horizontal angles, correcting of, discussed	563
Horizontal parallax, described	549
Horizontal refraction, defined	544
Hour(s), unit of time	469
Hour circle, defined	453
Hyperbola, described	398
Hypotenuse, of right triangle, defined	392
Indefinite integral, described	417
Independent variable, described	414
Index correction, sextant altitude, discussed	540
Index of refraction, defined	542
Infinite number, defined	375
Infinitesimal number, defined	375
Inscribed angle, of circle, defined	395
Inscribed circle, of triangle, described	392
Instrument correction, sextant altitude, discussed	540
Integral, of mathematical expression, defined	416
Integration, process of, discussed	416–417
Intended track line, defined	447
Interior angle, of triangle, defined	392
International Nautical Mile, defined	446
Interpolation, defined	419
general comments	427–428
introduction	419
Interpolation tables, discussed	425–427
Inverse sine, described	408
Irradiation, sextant altitude correction, defined and discussed	546
Isogrivs, defined	449
Isosceles triangle, defined	391
Julian day, use of	469
June solstice, defined	457
Knot, defined	446
Land mile, defined	446
Lapse rate, defined	551
Latitude, defined	445
Latitude and longitude, length of degree, table 6	124–125
explanation of table 6	5
Latitude and longitude factors, table 26	162–168
explanation of table 26	12
Latitude by meridian transit, finding time of	535–537
meridian altitudes, discussed	531–535
solutions of	531–537
Leg(s), of isosceles triangle, defined	391
of right triangle, defined	392
Line, in geometry, defined	390
Line of position, plot of, discussed	568
Linear, defined	419–420
Linear interpolation, discussed	419–421
Local apparent noon, by meridian transit, discussed	536–537
defined	479
Local apparent time, defined	478
Local hour angle, defined	455, 459
discussed	481
Local hour angle and meridian angle, finding of	567
Local mean time, discussed	477–478
Local sidereal time, defined	480
Local time, defined	467
Logarithm(s), discussed	381–383
of numbers, table 32	233–251
explanation of table 32	14–15
of trigonometric functions, table 33	252–296
explanation of table 33	15
various kinds of, discussed	384–385
Logarithmic function, defined	403
Logarithmic time-speed-distance nomogram, explained	611–613
Longitude, defined	445
Long-term almanac	687–692
Low altitude, observation corrections for	558–562
Low water, defined	599
Lower branch, celestial meridian, defined	453
meridian of earth, defined	443
Loxodrome, defined	446
Loxodromic curve, defined	446
Luminous range, defined	617
Luminous range diagram, discussed	618–621
Lunar day, defined	467
Lunar time, defined	467
Lune, of a sphere, defined	399
Lunicurrent interval, defined	600
Magnetic compass error, discussed	623
Magnetic course, defined	447
Magnetic north, defined	623
Mantissa, of logarithm, defined	382
March equinox, defined	456
Marine sextant corrections, discussed	554
Mathematical expression, defined	387
Mean high water lunitidal interval, tidal information	600
Mean refraction, defined	543
Mean sidereal time, defined	479
Mean solar time, defined	467
Mean sun, defined	478
Measured mile, speed table for, table 18	146
explanation of table 18	9
Median, of triangle, defined	392
Mental arithmetic, discussed	385–386
Mercator sailing, defined	571
discussed	580–582
Meridian, defined	443
Meridian angle, defined	455, 459
discussed	481
Meridian angle and altitude of body on prime vertical, table 25	158–161
explanation of table 25	11–12
Meridional parts, table 5	115–123
explanation of table 5	4–5
Meters, feet, and fathoms conversion, table 21	153
explanation of table 21	10
Microsecond, defined	469
Mid latitude, discussed	445
Middle latitude, discussed	445
Mid-latitude sailing, defined	570
Middle-latitude sailing, defined	570
discussed	575–580
Midnight, defined	467–468
Millimicrosecond, defined	469
Millisecond, defined	469
Minuend, defined	378
Minute(s), unit of arc	401
unit of time	469
Miscellaneous data, area	639
astronomy	639–640
charts	641
earth	641–644
length	644–645
mass	645
mathematics	645–646
meteorology	646

Page

Miscellaneous data—Continued
pressure 646–647
speed 647–648
volume 648–649
volume-mass 649
Mistake(s), navigational, defined 430
discussed 438–439
Mixed decimal, characteristic of, defined 382
Moonrise and moonset, finding time of 525–531
Most probable position, discussed 436–438
Multiplicand, defined 379
Multiplication, by logarithms, explained 383
of mathematical expressions, discussed 387–388
of numbers, explained 379–380
Multiplier, defined 379

Nadir, defined 453
Nanosecond, defined 469
Naperian logarithms, defined 384
Napier, Rules of Circular Parts, discussed 411–412
Natural logarithms, defined 384
Natural trigonometric function(s), defined 403
table 31 188–232
explanation of table 31 14
Nautical Almanac, extracts from 651–667
sextant altitude corrections by 555–556
Nautical and statute mile conversion, table 20 152
explanation of table 20 10
Nautical day, defined 468
Nautical mile, defined 446
Navigation accuracy, discussed 439
Navigational coordinates, table of 650
Navigational errors, combinations of, discussed 433–436
definitions of 429–430
introduction 429
miscellaneous, discussed 439–440
Navigational triangle, defined and discussed 464–466
Negative altitude, of celestial body, defined 461
Negative angle, defined 407
Negative number, defined 375
Nominal range, defined 617
Nonlinear interpolation, discussed 424–425
Normal, in geometry, defined 390
Normal curve, of random errors, discussed 432
Numbers, expressing, discussed 375–376
Numerator, defined 375

Oblate spheroid, defined 400, 443
Oblique angle, defined 390
Oblique coordinates, defined 401
Oblique plane triangles, solution of 409–410
Oblique spherical triangles, solution of 412
Oblique triangle, defined 392
Observed altitude, defined 540, 567
Obtuse angle, defined 390
Obtuse triangle, defined 392
Octagon, defined 393
Octant, of circle, defined 394
Offsets, table of, table 4 114
explanation of table 4 4
Ordinate, coordinate, described 401
Origin, of coordinate system, described 401

Parabola, described 397
Parallactic angle, described 465
Parallax, sextant altitude correction, discussed 549–550

Page

Parallax in altitude, described 549
Parallel, on earth, defined 444
Parallel lines (surfaces), defined 390
Parallel of altitude, defined 461
Parallel of declination, defined 454, 458
Parallel of latitude, on earth, defined 444
Parallel sailing, defined 570
discussed 574–575
Parallelogram, defined 393
Parentheses, use of in algebra 387
Pentagon, defined 393
Perimeter, of circle, defined 394
of cylinder, defined 396
of polygon, defined 393
Periodic error, discussed 433
Perpendicular lines (surfaces), defined 390
Personal correction, sextant altitude, discussed 540
Phase correction, sextant altitude, discussed 547
Place(s), in logarithms 382
in multiplication 379
Plane, defined 390
Plane geometry, defined 389–390
Plane sailing, defined 570
discussed 571–573
Plane surface, defined 390
Plane triangle, defined 391
Plane trigonometry, defined 401
useful formulas 413–414
Point, in geometry, defined 390
Point of tangency, described 395
Polar axis, of earth, defined 443
Polar coordinates, defined 401
Polar distance, defined 458
Polar grid, discussed 448–449
Polar horizontal parallax, defined 549
Polaris, latitude by, discussed 537–539
Polaris correction table, *Air Almanac*, discussed 539
Pole(s), of circle on sphere, defined 399
origin of coordinate system, described 401
Polygon(s), defined and discussed 393–394
Polyhedron(s), defined and discussed 395–396
Position angle, described 465
Position on the earth, discussed 444–445
Positive number, defined 375
Power, of number, defined 380
Precision, navigational, defined 430
Precision and accuracy, discussed 376–377
Predictability, of navigation system, defined 439
Predictable accuracy, of navigation system, defined 439
Predictions, of tides and currents, discussed 600
Pressure, unit conversions, table 14 140
explanation of table 14 8
Primary, great circle as, defined 399
Prime meridian, defined 443
Prime vertical, defined 461
Prime vertical circle, defined 461
Principal vertical circle, defined 460–461
Prism, defined 395
Probable error, navigational, defined 432
discussed 432, 439
Product, of multiplication, defined 380
Prolate spheroid, defined 400
Proportion, defined 389
Pub. No. 214, extracts from 698–700
Pub. No. 260, extracts from 693–695
Pub. No. 261, extracts from 696–697
Pyramid, defined 395

	Page
Quadrant, of circle, defined	394
Quadrantal spherical triangle, definition and solution of	411–412
Quadrilateral, defined	393
Quintant, of circle, defined	394
Quotient, of division, defined	381
Radar horizon, discussed	621–622
Radian, defined	401
Radical sign, defined	381
Radius (radii), of circle, defined	394
of sphere, defined	399
Radius vector, described	401
Raising to a power, multiplication, explained	380
Random errors, defined and discussed	432–433
Range of lights, discussed	617–621
Range of tide, defined	599
Ratio, defined	389
Ratio and proportion, discussed	389
Rational horizon, defined	460
Reciprocal(s), of number, defined and discussed	377
of vector, defined	386
Rectangle, defined	393
Rectangular coordinates, described	401
Rectangular error, described and discussed	433
Reduction to the meridian, process of, discussed	535
Reference direction, described	623
Reference stations, tides and currents	600
Reflex angle, defined	390
Refraction, sextant altitude correction, defined and discussed	542–545
Regular polygon, defined	393
Regular prism, defined	395
Regular pyramid, defined	395
Relative accuracy, of navigation system, defined	439
of number, defined	376
Relative bearing, discussed	447–448
Relative humidity, table 16	142–143
explanation of table 16	8–9
Relative precision, of number, defined	376
Remainder, of division, described	381
Repeatability, of navigation system, defined	439
Repeatable accuracy, of navigation system, defined	439
Repeating decimal, notation for	381
Residual deviation, defined	624
Resultant, vector, described	386
Rhomboid, defined	393
Rhombus, defined	393
Rhumb line, defined	446, 582
Rhumb lines and great circles, discussed	582–583
Right angle, defined	390
Right ascension, defined	454
Right cone, defined	397
Right cylinder, defined	396
Right line, defined	390
Right plane triangles, solution of	409
Right prism, defined	395
Right pyramid, defined	395
Right spherical triangles, solution of	411
Right triangle, defined	392
Rising, setting, and twilight, discussed	523
finding times of	523–531
Rising, setting, and twilight at moving craft, discussed	531
Root mean square, discussed	439
Rounding off, of numbers, discussed	377
Sailing(s), discussed	570–571
Scalar, defined	386
Scalars and vector quantities, discussed	386
Scalene triangle, defined	392
Sea-air temperature difference correction, sextant altitude, discussed	550–551
Secant, of circle, defined	395
of curve, described	415
Second(s), unit of arc	401
unit of time	469
Second differences, nonlinear interpolation, discussed	425
Second estimate, meridian transit, discussed	536
Secondaries, great circle as	399
Sector, of circle, defined	394
Segment, of circle, defined	394
Semicircle, defined	394
Semidiameter, of circle, defined	394
of sphere, defined	399
sextant altitude correction for, discussed	546–547
Sensible horizon, described	460
September equinox, defined	457
Seven-tenths rule, defined	616
Sexagesimal system, angular length, defined	401
Sextant, altitude measuring device	540
of circle, defined	394
Sextant altitude, defined	540
sight reduction	567
Sextant altitude correction(s), need for, discussed	540
order of applying	554
summary of, discussed	553–554
Side(s), of polygon, defined	393
of triangle, defined	391
Sidereal day, defined	468
Sidereal hour angle, defined	454, 458
Sidereal noon, defined	468
Sidereal time, defined	467
discussed	479–480
Sight reduction, complete solution of	568–569
definition and introduction	566
Sight reduction tables, defined	566
Sign, of number, defined	375
Significant digits, defined	375
Similar triangles, defined	392
Single interpolation, defined and discussed	419–422
Slack water, defined	599
Slide rule, discussed	385
Small circle, of sphere, defined	399, 443
Solar parallax, defined	550
Solar time, defined	467
Solid, in geometry, defined	390
Solid geometry, defined	390
Space coordinates, defined	401
Speed, defined and discussed	446
Speed, time, and distance, table 19	147–151
explanation of table 19	9
Speed made good, defined	446
Speed of advance, defined	446
Speed of tidal current, finding of for any time	606–607
Speed over ground, defined	446
Sphere(s), defined and discussed	399–400
Spherical coordinates, defined	401
Spherical triangle, defined	399, 464

	Page
Spherical trigonometry, defined	401
useful formulas	413–414
Spheroid, defined	400
Square, a number, defined	380
a rectangle, defined	393
Square root, of number, defined	381
Stand, of tide, defined	599
Standard, navigational, defined and discussed	430
Standard deviation, defined and discussed	432
Standard time, defined	473
Statute mile, defined	446
Stellar parallax, defined	549
Straight angle, defined	390
Straight line, defined	390
Sub -astral, -lunar, -satellite, -solar, -stellar } point	465
Subordinate stations, tides and currents	601
Subtraction, arithmetic and algebraic, defined	379
of mathematical expressions, discussed	387
of numbers, explained	378–379
Subtrahend, defined	378
Sum, of numbers, defined	378
Summer solstice, defined	457
Summer time, defined	473–474
Sunrise and sunset, finding time of	523–524
Superior, use of in multiplication, explained	380
Supplement, of angle, defined	391
Supplementary angles, defined	391
Surface, defined	390
Symbols, for navigational positions	637
mathematical	637
discussed	387
miscellaneous	638
of celestial bodies	637
zodiacal	637
Systematic errors, defined and discussed	431
Tangent, to circle, defined	395
Temperature, conversion of, table 15	141
explanation of table 15	8
Terrestrial refraction, defined	543
Tidal current, defined	599
Tidal current charts, described	600
Tidal current predictions for reference stations, discussed	605
Tidal current predictions for subordinate stations, discussed	605–606
Tidal current tables, discussed	605
extracts from	704–707
Tidal day, defined	467
Tidal effects, discussed	599–600
Tide, defined	599
Tide predictions for reference stations, discussed	601
Tide predictions for subordinate stations, discussed	601–602
Tide rips, defined	600
Tide tables, discussed	600–601
extracts from	701–703
Time, expressing, discussed	468–469
kinds of, discussed	467–468
Time and arc, discussed	469–471
Time and hour angle, discussed	480–481
Time and longitude, discussed	471
Time diagram, described	459
Time measurements and conversions, introduction	467
Time meridian, defined	472
Time zone, defined	472
Time zones, zone descriptions, and suffixes, table 36	370
explanation of table 36	16
Toward, sight reduction, defined	567
Track, defined	447
Transposition, defined and discussed	389
Transversal, defined	391
Trapezoid, defined	393
Traverse, defined	573
Traverse sailing, defined	570, 573
discussed	573–574
Traverse table(s), discussed	571
table 3	24–113
explanation of table 3	4
Triangle(s), defined and discussed	391–393
solution of	409–412
Trigonometric functions, discussed	402–404
in various quadrants, discussed	404–408
inverse, discussed	408
of small angle, discussed	414
Trigonometric identity, defined	407
Trigonometry, defined	401
definitions of	401
principles of	401–414
Triple interpolation, defined	419
discussed	423–424
Triquadrantal spherical triangle, definition and solution of	411–412
True course, defined	447
True wind, direction and speed of, table 10	136–137
explanation of table 10	6
Truncated cone, defined	397
Truncated pyramid, defined	395
Twilight, finding time of	524–525
U-shaped error, explained	433
Uncorrected errors, sextant altitude, discussed	551–553
Uncorrecting, compass conversion, defined	625
Undivided astronomical triangle, altitude, solving for	492–497
altitude azimuth, solution	499–500
altitude azimuth by haversines	503
altitude by cosine-haversine formula	502
azimuth, solving for	497–498
azimuth by haversines	502–503
haversine formulas	501
meridian angle, solving for	503–505
parallactic angle, solving for	505
solutions of	492–505
time and altitude azimuth, solution	500–501
time azimuth, solution	498–499
Universal Time, defined	472
Upper branch, celestial meridian, defined	453
meridian of earth, defined	443
Variable, defined	414
Variation, defined	623
Variation and deviation, applying, discussed	624–626
Vector(s), addition and subtraction of, explained	386
defined	386
principles of	386
Vector quantity, defined	386
Velocity vectors, use of	386

	Page
Vernal equinox, defined	456
use of in locating an hour circle	454
Vertex, of angle, described	390
of great circle, defined	583
of parabola, described	398
of triangle, defined	391
Vertical angles, defined	391
Vertical circles, defined	460
Vertices, of triangle, defined	391
Visible horizon, defined	459
War time, defined	474
Watch error, defined	475
Watch time, defined and discussed	475–477
Winter, solstice, defined	457
Zenith, defined	453
Zenith distance, defined	461
Zone description, defined	472
Zone meridian, defined	472
Zone time, discussed	472–474
